1 **A three-pressure-sensor (3PS) system for monitoring ankle supination torque**  
2 **during sport motions**

3

4 **Abstract**

5 This study presented a three-pressure-sensor (3PS) system for monitoring ankle  
6 supination torque during sport motions. Five male subjects wore a pair of cloth sport  
7 shoes and performed ten trials of walking, running, cutting, vertical jump-landing and  
8 stepping-down motions in a random sequence. A pair of pressure insoles (Novel Pedar  
9 model W, Germany) was inserted in the shoes for the measurement of plantar pressure  
10 at 100 Hz. The ankle joint torque was calculated by a standard lower extremity  
11 inverse dynamic calculation procedure with the data obtained by a motion capture  
12 system (VICON, UK) and a force plate (AMTI, USA), and was presented in a  
13 supination/pronation plane with an oblique axis of rotation at the ankle joint. Stepwise  
14 linear regression analysis suggested that pressure data at three locations beneath the  
15 foot were essential for reconstructing the ankle supination torque. Another group of  
16 five male subjects participated in a validation test with the same procedure, but with  
17 the pressure insoles replaced by the 3PS system. Estimated ankle supination torque  
18 was calculated from the equation developed by the regression analysis. Results  
19 suggested that the correlation between the standard and estimated data was high ( $R =$   
20  $0.938$ ). The overall root mean square error was  $6.91\text{Nm}$ , which was about 6% of the  
21 peak values recorded in the five sport motions ( $113\text{Nm}$ ). With the good estimation  
22 accuracy, tiny size and inexpensive cost, the 3PS system is readily available to be  
23 implanted in sport shoe for the estimation and monitoring of ankle supination torque  
24 during dynamic sport motions.

25

26 **Keywords:** Ankle sprain, biomechanics, joint moment, kinetics, inversion

27

## 28 **Introduction**

29 Ankle sprain is a common sport injury (Fong et al., 2007a) which may lead to ankle  
30 instability (Yeung et al, 1994). In a recent world consensus conference on ankle  
31 instability in September 2004, over twenty world renowned orthopaedic specialists  
32 concluded that there was still no general consensus to treat ankle instability (Chan and  
33 Karlsson, 2005). The experts added that instead of paying tremendous effort in  
34 treating ankle instability, the prevention of ankle sprain injury would be the  
35 appropriate research direction in solving the problem.

36

37 Different prophylactic approaches were employed to prevent ankle sprain injury,  
38 however, the prevalence is currently still significant. A recent epidemiology study  
39 showed that ankle sprain injury is still a common sport-related trauma, accounting for  
40 12% of all attendance in an accident and emergency department (Fong et al, in press).  
41 This suggested a room for alternative measures for preventing ankle sprain injury in  
42 sports. Recently, there is an innovative attempt to design an intelligent “sprain-free  
43 sport shoe” for the purpose (Chan, 2006). The shoe first senses the ankle supination  
44 torque, then identifies if there is a significant injury risk, and finally initiated  
45 corrective action to protect the ankle joint. This study presented a  
46 three-pressure-sensor (3PS) system which serves the purpose to monitor the ankle  
47 supination torque during sport motions.

48

## 49 **Method**

### 50 Development test

51 Five right-legged male subjects (age =  $23.0 \pm 3.0$  yr, height =  $1.72 \pm 0.03$  m, body  
52 mass =  $65.1 \pm 9.7$  kg, foot length = 255-260 mm) wore a pair of cloth sport shoes

53 (Fong et al., 2007b) and performed ten trials of walking, running, 45-degree cutting,  
54 vertical jump-landing and stepping-down (from a block) motions in a random  
55 sequence in a biomechanics laboratory. The university ethics committee approved the  
56 study. Twelve reflective markers were attached at the hallux, distal first metatarsal,  
57 distal fifth metatarsal, proximal first metatarsal, proximal fifth metatarsal, navicular,  
58 medial calcaneus, lateral calcaneus, heel, lateral malleolus, tibial tubercle, and lateral  
59 femoral epicondyle, either on the skin or shoe surface. The essential anthropometric  
60 data was measured by an anthropometer for the ankle joint torque calculations  
61 (Vaughan et al., 1992). A pair of pressure insoles (Novel Pedar model W, Germany)  
62 was used for measuring the plantar pressure at 99 positions covering the whole plantar  
63 area at 100 Hz. Each subject performed the motion and stepped with their right foot  
64 on a force plate (Advanced Mechanical Technology Inc., USA), which sampled the  
65 data at 1000 Hz.

66

67 The collected data were trimmed from the moment of take off before the foot strike on  
68 the force plate, until the next take off from the force plate. For jump-landing and  
69 stepping-down motions, the data was trimmed until one second after the foot strike as  
70 there was no another take off. The force plate data were re-sampled to every 0.01s to  
71 match the frequency of the pressure data. The ankle joint torque was calculated by a  
72 standard lower extremity inverse dynamic calculation procedure (Vaughan et al.,  
73 1992). The torque was presented in a supination/pronation plane with an oblique  
74 rotation axis tilting 42 degrees upward and 23 degrees medially from the  
75 perpendicular axes of the foot (Hertel, 2002). Resultant linear acceleration at nine  
76 positions (hallux, distal first metatarsal, distal fifth metatarsal, proximal first  
77 metatarsal, proximal fifth metatarsal, navicular, medial calcaneus, lateral calcaneus,  
78 heel), and the resultant angular velocity at the foot segment center of mass were

79 obtained from the motion capture system (VICON, UK).

80

81 Data from all trials, all motions and all subjects were pooled together for stepwise  
82 linear regression analysis to reconstruct the value of the ankle supination torque  
83 (SupT) by the value of the 99 pressure sensors (P1, P2, ..., P99, unit = N/cm<sup>2</sup>), the  
84 resultant linear acceleration at the nine positions (unit = m/s<sup>2</sup>), and the resultant  
85 angular velocity at the foot segment center of mass (unit = deg/s). A linear regression  
86 was performed as a linear relationship was expected between the ankle supination  
87 torque and each of these predictors. In each analysis, predictors were added to the  
88 regression models until the inclusion of the next predictor showed redundancy, as  
89 indicated by a tolerance value of less than 0.20.

90

91 The analysis suggested that only three pressure data (Figure 1) were essential to  
92 reconstruct the ankle supination torque, with an explained variance of 0.831 (adjusted  
93 R<sup>2</sup>). The three locations were approximately at the fourth/fifth metatarsalphalangeal  
94 joint (Position 60), the third metatarsalphalangeal joint (Position 72), and the  
95 second/third distal phalange (Position 98). The linear acceleration and angular  
96 velocity were not essential. The regression model is shown as follow, with PX as the  
97 value of pressure of the sensor at position X, in N/cm<sup>2</sup>.

98

$$99 \quad SupT (Nm) = -2.068 + 0.910 \times (P60) + 1.318 \times (P72) + 1.549 \times (P98) + error$$

100

#### 101 Validation test

102 A three-pressure-sensor (3PS) system (Sengital, Hong Kong) with three individual  
103 circular pressure sensors (Interlink Electronics, Force Sensing Resistor Model 400,

104 USA) implanted to the three positions beneath an insole in a sport shoe (Dr Kong  
 105 Footcare Limited, C70135) was fabricated (Figure 1b-d). The pressure sensors were  
 106 5.0mm in diameter and 0.30mm in thickness, and the price of each sensor was about  
 107 US 1-2 dollars. The instrumented insole was calibrated with a pressure calibration  
 108 device (Novel Trublu, Germany) in the range of 0-60 N/cm<sup>2</sup> (Figure 2). The pressure  
 109 sensors output a 10-bit digital signal (0-1023), and the calculation of the estimated  
 110 ankle supination torque ( $SupT_{estimated}$ ) is represented by the following equation, with  
 111 SX as the sensor signal at position X (unit-less, range = 0-1023).

112

$$\begin{aligned}
 SupT_{estimated} (Nm) = & -2.068 + 0.00190827 e^{0.01252(1023-S60)} \\
 & + 0.002763846 e^{0.01252(1023-S72)} \\
 & + 0.003248253 e^{0.01252(1023-S98)}
 \end{aligned}$$

113

114

115 Another group of five right-legged male subjects (age = 23.8 ± 3.3 yr, height = 1.74 ±  
 116 0.03 m, body mass = 65.4 ± 7.3 kg, foot length = 255-260 mm) participated in the  
 117 validation test. Independent t-tests showed that the two groups of subjects did not  
 118 differ in age, height and body mass (p > 0.05). The same procedure in the  
 119 development experiment was conducted, with only the 99-sensor pressure insoles  
 120 replaced by the 3PS system to estimate the ankle supination torque ( $SupT_{estimated}$ ).  
 121 Data from all trials were pooled together, and the correlation coefficient (R) and the  
 122 root mean square error (RMS error) were computed between the standard ( $SupT$ ) and  
 123 estimated data ( $SupT_{estimated}$ ).

124

## 125 **Results**

126 Table 1 shows the good accuracy of the ankle supination torque estimation. The

127 correlation was high in most individual motion and subject ( $R > 0.80$ ). In overall, the  
128 correlation between the standard and estimated data was 0.938. The overall RMS  
129 error was 6.91Nm, which was about 6% of the peak values recorded in the motions  
130 (113Nm).

131

132 Figure 3 shows the pattern and the absolute error of the standard and estimated data of  
133 one selected trial in each motion, which has an average accuracy among all trials. In  
134 general, the estimated data followed the pattern of the standard data well, even for the  
135 instable period during the first 0.40s after landing in cutting motion. The estimation  
136 was in-phase during the fluctuating period, indicating that the 3PS system is sensitive  
137 to the trend of changes. The peak magnitudes of the estimated values were about  
138 95-105% of that of the standard data in all motions, indicating a very good estimation  
139 of the peak values.

140

#### 141 **Discussion**

142 Forner Cordero and coworkers presented a method to calculate joint torque from  
143 limited ground reaction force information from pressure insoles (Forner Cordero et al.,  
144 2004, 2006). They reported very good accuracy in calculating ankle joint torque, as  
145 indicated by a small RMS error (3.177Nm to 5.758Nm). In this study, although the  
146 accuracy is slightly inferior, the new method involves only three individual pressure  
147 sensors and does not rely on motion capture system, and is readily available to be  
148 implanted in a sport shoe for real-time ankle supination torque measurement.

149

150 In this study, two groups of similar subjects were recruited to limit the variability of  
151 the nature of subject, in order to test the feasibility of the presented method. Future  
152 studies are necessary to generalize the method to other subject groups, or to establish

153 different methods for different subject groups. Besides, even within a homogeneous  
154 group of subject, the supination-pronation axis may still vary among each individual  
155 (Lundberg et al, 1989). This has to be considered in real application of the presented  
156 method. Another limitation is the lack of a spraining motion being tested. Including a  
157 spraining motion in laboratory would be unethical and also practically impossible. To  
158 cope with this, we intended to select five representative motions in most sports,  
159 especially in cutting and jump-landing motions which most commonly involve ankle  
160 sprain injury. Yet we may not be able to estimate the ankle supination torque during a  
161 real sprain, we could monitor the magnitude and check if it is approaching to injury.  
162 Future studies should contribute by suggesting an ankle supination torque threshold in  
163 order to identify significant ankle sprain risk.

164

165 This study presented a three-pressure-sensor (3PS) system that could estimate the  
166 ankle supination torque during various dynamic sport motions with good accuracy.  
167 The system is inexpensive and tiny, and could be implanted into a sport shoe. The  
168 device serves as a platform for a recently developed “sprain-free sport shoe” for  
169 real-time monitoring of ankle supination torque and the subsequent ankle sprain injury  
170 risk.

171

## 172 **Acknowledgement**

173 This study was financially supported by the Innovation Technology Fund from the  
174 Innovation and Technology Commission, Hong Kong Special Administrative Region  
175 Government, Project Number: ITS/015/06. The authors acknowledge Dr Alan  
176 Hiu-Fung Lam and Mr Joe Chi-Yin Wong of Sengital Limited to provide technical  
177 assistance in the development of the three-pressure-sensor (3PS) system for this study.

A three-pressure-sensor (3PS) system for monitoring ankle supination torque during sport motions

Journal of Biomechanics

Dear Professor Chan,

Thank you for your submission to the Journal of Biomechanics. After considering the enclosed reviews from our referees, I regret to inform you that our referee panel recommends against publication of your manuscript in its current form, although a revised manuscript may be resubmitted and considered after further review.

Although it is obvious your manuscript represents considerable work, and the referees and I believe it to be relevant to the Journal, the referees raised several major issues that would need to be addressed prior to publication. In general, the referees were enthusiastic about the potential of your study, but raised several major concerns. Their comments are attached for your information.

Perhaps most importantly is whether your work is published as an Original Article or a Short Communication. Published guidelines state Original Articles "typically explore some explicit biological hypothesis or report original but substantial observations or data of broad utility. Conceptually but novel experimental or computational methods may be submitted as Original Articles when their relevance and importance for research or biological questions is demonstrated or otherwise emphasized in the text." A Short Communication, on the other hand reports "preliminary observations, simple new techniques or devices, calibrations/validations, or points of historical interest." Currently, your material best fits the guidelines of a "Short Communication". My sense from the reviewers is that without additional data, your manuscript should be reformatted to adhere to the guidelines for a short communication (<1500 words, 3-4 figures).

Please note that in consideration of the authors' and the reviewers' time, I normally allow only one major revision; if the reviewers request another major revision, I regret that we will not be able to publish your manuscript. Unfortunately, we have been forced to decrease our acceptance rate significantly due to an increase in manuscript

submissions.

To submit a revision, go to <http://ees.elsevier.com/bm/> and log in as an Author. You will see a menu item called Submission Needing Revision. You will find your submission record there. Please update accordingly and submit your revised manuscript."

If you choose to submit a revised manuscript, please provide a list of points of how you have responded to the reviewers' suggestions with the revised manuscript, at your earliest convenience. If you do not wish to proceed, please let us know in order to complete our records. The maximum time allowed for revision is 8 weeks, after which the file on this manuscript will be closed. If you feel you need longer than this please contact me.

Please note:

- \* Any figures and tables should be included, even if these are unaltered.
- \* It is the author's responsibility to ensure that data presented in figures and tables agree with that provided in the text. Please cross check figures, tables and text carefully.
- \* Please double-check formatting of your references
- \* Please use your word processor to automatically number the lines of your manuscript

Thank you again for submitting to the Journal of Biomechanics. I look forward to receiving your revised manuscript.

Yours sincerely,

Farshid Guilak, Ph.D.  
Editor-in-Chief  
Journal of Biomechanics

Reviewers' comments:

## **Reviewer #1: Summary**

The manuscript presents a new method for measuring ankle supination torque during sport activities using the 3PS. Two studies are presented: a development study, during which plantar pressures and ankle joint torques were sampled in five subjects using pressure insole and optoelectronic tracking + forceplate during several sports motions, and a validation study, during which the same experimentation was repeated in another group of five subjects, replacing the insole by the 3PS. The results show a good correlation and acceptable rmse between estimated and inverse dynamics data.

The work is interesting and innovative. However, several aspects would benefit from modification /more detailed description or discussion.

### **Specific comments**

**The reviewer regrets the absence of page numbering (requested in the guide for authors).**

>>> Page and line numbers are added accordingly.

**The methodology section could provide more details about the 3PS. For instance, some technical specifications regarding the sensors are found much later in the discussion.**

>>> The size and price of the sensors are moved to the methods (Page 6, Line 105-107).

**The reviewer does not understand the link between the systematic review paper by Fong et al (2007) and the cloth sport shoes.**

>>> The reference of the cloth sport shoe was incorrect. The correct one was missed. It was included in the revised manuscript.

**The authors reference the review by Hertel (2002) to define the orientation of the axis of pronation-supination. The angles to the horizontal and sagittal plane mentioned here are those reported in by Inman (). In this respect, it seems useful to discuss (a) the way the perpendicular axes of the foot were determined in the present study, and (b) the issue of the individual variability of this axis (for instance Lundberg (1989) showed that the medial deviation of the axis averaged 18°, but with a standard deviation of over 16°), and its implication on the validity of their study.**

>>> (a) The perpendicular orthogonal axes were determined with Vaughan et al's method (1992). The inversion/eversion axis was first defined as the vector from the virtual ankle coordinate to the toe tip. Secondary, by crossing the inversion/eversion axis of the foot segment to the medial-lateral axis of the shank segment, the internal/external rotation axis at the ankle joint was obtained. Finally, by crossing the internal/external rotation axis to the inversion/eversion axis, the plantarflexion/dorsiflexion axis at the ankle joint was obtained. We believe that the readers could refer to Vaughan's handbook for full reference, and thus we did not attempt to list all the details in the paper. (b) Discussion on the individual variability of the pronation-supination axis is added.

**In the discussion, it would be useful to discuss the initial fluctuation/instable period, considering the aim of developing a "sprain-free sport shoe". In this respect, issues regarding reaction time, for instance, should be considered and the feasibility of the approach discussed.**

>>> The estimated pattern followed the standard supination torque well, as it showed and in-phase fluctuation pattern. Such in-phase pattern indicated that the system could monitor the trend of changes without much delay. Moreover, the peak value of the estimation was about 95-105% of the standard data. All these suggested that the estimation was very good. This is revised in the first paragraph in Discussion: "The estimation could also show the instable period during the first 0.40s after landing in cutting motion, as indicated by an in-phase fluctuating pattern of ankle supination torque. The in-phase estimated pattern indicated that the system could monitor the trend of changes without much delay. For the magnitude of the peak value, the estimated values were about 95-105% in all motions."

**Please use "calcaneus" instead of "calcaneous".**

>>> Corrected accordingly.

**The verb "to encounter" means "to meet" and not "to pool or put together".**

>>> Corrected to "pooled together".

**The term "real" is used at several instances in the manuscript to characterise the torque computed using inverse dynamics. This is an estimate, it may of course serve as a gold standard here, but confusion should be avoided.**

>>> The term "real ankle supination torque" is revised to be "standard ankle supination torque".

**In the discussion, the unit (probably seconds) of the instable period is missing.**

>>> Corrected accordingly.

**Reviewer #2:**

This study developed a three-pressure-sensor (3PS) system for monitoring ankle supination torque during sport motions. Five male subjects wore a pair of cloth sport shoes and performed ten trials of walking, running, cutting, vertical jump-landing and stepping-down motions in a random sequence. A pair of pressure insoles (Novel Pedar model W, Germany) was inserted in the shoes for the measurement of plantar pressure at 100 Hz. The ankle joint torque was calculated by a standard lower extremity inverse dynamic calculation procedure with the data obtained by a motion capture system (VICON, USA) and a force plate (AMTI, USA), and was presented in a supination/pronation plane with an oblique axis of rotation at the ankle joint. Stepwise linear regression analysis suggested that pressure data at three locations beneath the foot were essential for reconstructing the ankle supination torque. Another group of five male subjects participated in a validation test with the same procedure, but with the pressure insoles replaced by the 3PS system. Estimated ankle supination torque was calculated from the equation developed by the regression analysis. Results suggested that the correlation between the real and estimated data was high ( $R = 0.938$ ).

**This is generally a good study but overall has insufficient data for a full paper. I think it is better suited as a technical note and should be shortened. There are few subjects (n=5) and no real question being tested.**

>>> This paper is trimmed to be a Short Communication with 1500 words.

Other issues:

**There is little description of the instrument.**

>>> As the paper is further trimmed to a Short Communication, we could hardly describe the technical details of the instrument. However, we managed to describe the background principle and the method of calculation, and we are sure that reader could follow the method to fabricate their own similar system.

**There are a number of grammatical and stylistic errors that need correction.**

>>> We have checked again the grammar in the revised manuscript.

**Referee suggestion**

**Figure legends**

Figure 1 – (a) Location of the three pressure sensors (in right foot) required for the reconstruction of the ankle supination torque in the development test; (b) Three individual pressure sensors were attached to the required position beneath an insole; (c) The top side of the instrumented insole; (d) the sport shoe with the instrumented insole used in the validation test in this study.

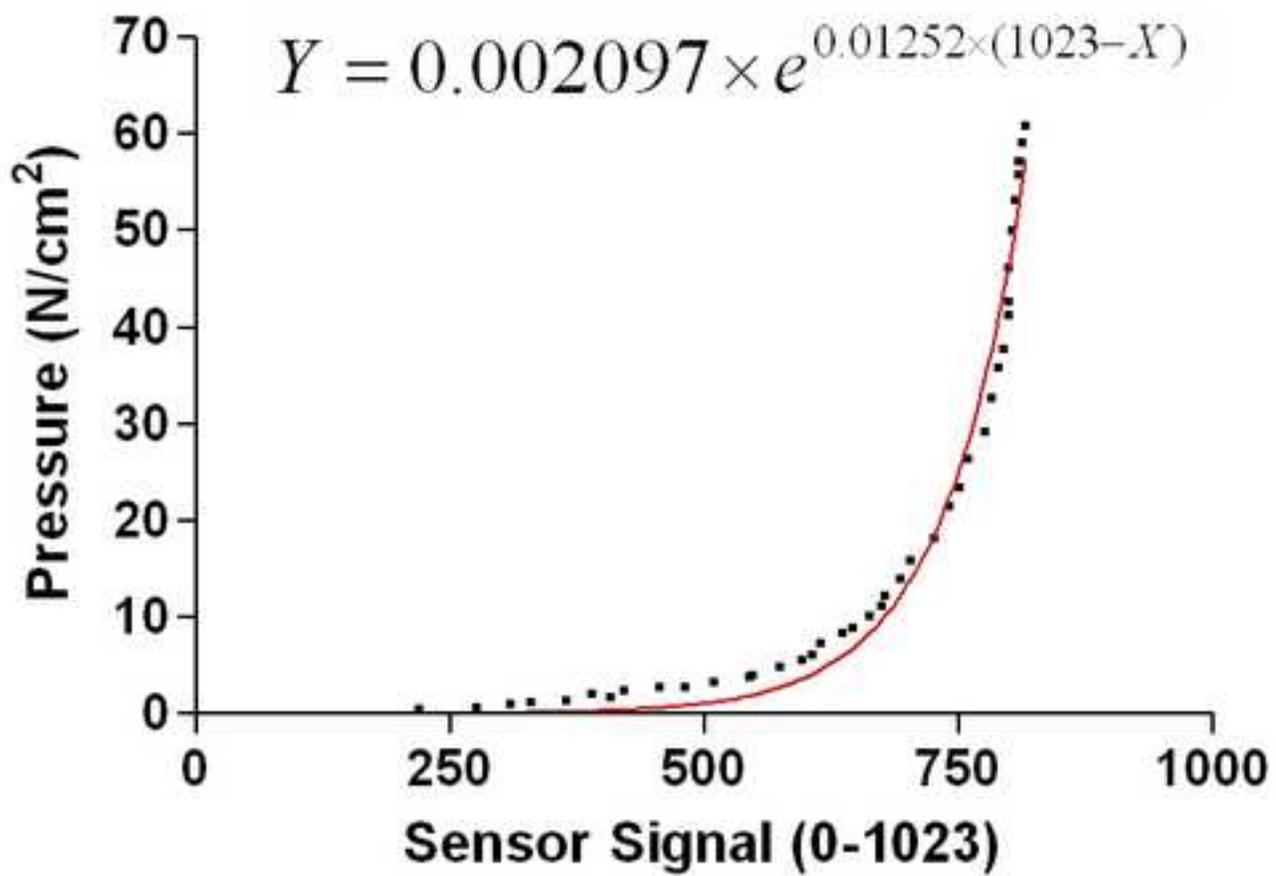

Figure 2 – Relationship between the applied pressure ( $\text{N}/\text{cm}^2$ ) and the output signal (unit-less, range = 0-1023) of the individual sensors in the instrumented insole with the numerical presentation.

Figure 3 – The pattern and the absolute error of the real (SupT) and estimated data (SupT<sub>estimated</sub>) of one selected trial in each motion with an average accuracy among all trials.

(a) Running

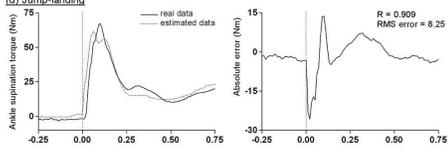

(b) Walking

(c) Cutting motion

(d) Jump-landing

(e) Stepping down

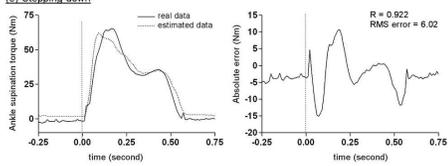

Table 1 – Accuracy of the ankle supination torque estimation as represented by the correlation (R) and the root mean square error (RMSE), and the peak torque value in all trials.

Motion	Subject 1		Subject 2		Subject 3		Subject 4		Subject 5		All subjects		Peak torque in all trials (Nm)
	R	RMSE	R	RMSE									
Running	0.980	3.95	0.983	5.77	0.980	6.99	0.980	7.87	0.947	10.42	0.961	8.78	113
Walking	0.990	1.94	0.993	1.70	0.988	2.35	0.980	3.42	0.972	4.27	0.978	3.29	51
Cutting	0.890	7.14	0.787	9.63	0.838	7.81	0.881	6.95	0.901	7.83	0.870	7.91	61
Jump-landing	0.903	7.57	0.914	6.37	0.909	6.75	0.920	5.61	0.898	9.67	0.899	8.16	104
Stepping-down	0.933	6.31	0.952	6.12	0.949	6.08	0.924	6.47	0.977	4.26	0.946	6.14	78
All	0.934	6.23	0.935	6.34	0.958	5.92	0.928	7.41	0.942	7.53	0.938	6.91	113
