APPENDIX 1

DESCRIPTION OF THE COMPUTER PROGRAM

## A1 - 1 Introduction

The computer program was written in 1900 CSL <sup>(1)</sup>, an ICL package for simulation applications and ran in the Loughborough University Computer Centre.

This version of CSL allows the user to provide his own statements and routines in standard Fortran IV, if desired. Because the ICL package would not provide for the use of antithetic numbers, there was a need to introduce routines and statements in Fortran within the CSL program. Those statements are indicated by an F in the first column of a statement.

The description of the simulation program will be made in four parts:

- i) An explanation about the components (segments) of the program (main program and subroutines)
- ii) A list with explanations of the major variables in the program
- iii) A series of flow charts corresponding to the main program and subroutines £ALLC, £BLLC and £STCT
- iv) The full listing of the main program and all subroutines

(1) -- CSL manual is edited by ICL, as technical publication 3386.

## A1 - 2 Components (segments) of the program

The CSL program is composed of a main program (MASTER MACH) and three subroutines (£ALLC , £BLLC and £STCT). Subroutines £ALLC and £BLLC are both used to sequence the jobs in queue and to load them into the machines. The difference between them relates to the fact that £ALLC is used for the priority rules which are designed to avoid setup times (FIFOM, FIFOMB, SLACKM and SPTM), while £BLLC is used for the priority rules which do not avoid setup times (FIFO, FIFOB, SLACK and SPT). Subroutine £STCT is used to control the inventory when it is switched-on.

Apart from those four CSL routines which were written by the author, a series of Fortran subroutines and functions were incorporated into the program in order to allow the generation of antithetic random numbers. Those routines belong to the NAG library of subroutines <sup>(2)</sup>, subgroup G05. They were slightly modified in order to serve the purposes of this study.

Below is a list of the Fortran routines adapted from the NAG library with their modified names and corresponding original names (NAG library names).

Modified name	Original NAG name (2)	OBJECTIVE
FADF	G05 ADF	To generate a random number from a standard normal distribution

(2) For description of those programs see the NAG LIBRARY MANUAL (Mark 4), NAG OXFORD (Subgroup G05).

(cont. )

Modified name	Original NAG name	OBJECTIVE
FAEF	G05 AEF	To generate a random number from a normal distribution with mean AM and standard deviation S
FABF	G05 ABF	To generate a random number from a uniform distribution in the range A, B
FACF	G05 ACF	To generate a random number from a exponential distribution with mean A
FAFF	G05 AFF	To generate a random number from a lognormal distribution with mean A and standard deviation B
FARF	G05 ARF	To determine the reference vector in a discrete distribution
FATF	G05 ATF	To determine the cumulative distribution for the discrete uniform distribution
FAVF	G05 AVF	To determine the cumulative distribution for the Poisson distribution
FAWF	G05 AWF	To determine the cumulative distribution of a histogram provided by the user
FAZF	G05 AZF	To return a pseudo random number from a required distribution

Apart from these 10 Fortran routines whose detailed description can be found in the NAG manual, there is an extra routine provided by the author, which allows the generation of antithetic random number. This routine is called SUBROUTINE MYRAN (P, NSTR) and works by generating a random number from the CSL internal random generator (Subroutine

IRAN1 in the Fortran translation), and calculating a random number as a function of the value of P and NSTR. When  $P = 1$  the routine generates a stream of 'straight' random number, but if  $P = -1$ , the routine generates an antithetic stream. The value of NSTR is used to indicate which stream of random numbers should be generated.

The modifications introduced in the 10 NAG routines consisted in creating a new argument (NSTR) to take account of the different streams, and generating the random streams from MYRAN, instead than from G05 AAF which is the internal random generator for the NAG library.

The main program and all the subroutines are stored in a filing system, in binary version, with all the data also stored in another file. In its present version the program runs in the following mode.

- i) The data which is on file is edited
- ii) The program reads those data and executes three antithetic pairs of runs in accordance with the sampling procedure described in chapter 5
- iii) The results of each antithetic pair are output through the line printer and to a file for posterior statistical analysis
- iv) If more than 3 pairs of antithetics is desired, the program can be submitted again such that in each submission the output of the program is stored in a different file which can be accessed later such that all antithetic pairs from different runs are put together for statistical analysis.

### A1 - 3 List of variables

In order to facilitate reference the variables will be divided into two groups. The first group is composed of the definition variables (entities) which constitutes the major structure of the model. These variables will be listed in order of their declaration in the main program (they are equivalent to their corresponding variables in the subroutines).

The second group of variables is composed of the input variables whose values are read as data. All data is read from the main program. These variables are going to be listed in accordance with the sequence in which they are input to the model (read).

#### A1 - 3.1 Definition variables (Entities)

##### 1. CLASS TIME ORDER,300 (3) SET CUSTQUEUE BSET POOLB

The entity ORDER represents the customer's orders. During the initialization all 300 entities are loaded in POOLB. It is assumed that no more than 300 ORDERS will be in the system at any one time. In case this happens the program is halted with a message: 'POOLB IS NOT ENOUGH'.

Each ORDER has three attributes:

ORDER.I(1) = The product style required

ORDER.I(2) = The number of different product sizes required

ORDER.I(3) = The total quantity ordered

(These three attributes do not need be initialized).

2. CLASS JOB. 900 (4) SET INQUEUE, ATQUEUE BSET POOL

Entities JOB represent the production batches for individual product sizes. At the initialization of each run all entities JOB are loaded in POOL. It is assumed that there will be no more than 900 entities JOB at the shop at any time. In case this number is reached the program is halted with a message:

'POOL IS NOT ENOUGH'. The sets 'INQUEUE' and 'ATQUEUE' are both used to handle JOBS arriving in the shop. The former is used during the arrival time of 'ORDERS' and the latter to keep the JOBS which are waiting to be loaded at the machines.

Each JOB has four attributes:

JOB.I(1) = Identification number of the ORDER to which  
the JOB belongs

JOB.I(2) = The product size

JOB.I(3) = The 'JOB' batch size

JOB.I(4) = The code number of the product represented by  
this JOB. This code number is used to identify  
the moulds which are able to manufacture the  
particular product represented.

(Those values do not need to be initialized).

3. CLASS TIME MACHINE . 2(2) BSET IDLE, BUSY

Entities MACHINE represent individual multiple stations machines. At the initialization of each run all machines which are in operation are loaded into set 'IDLE'. Each machine has two attributes:

MACHINE . I(1) An on-off attribute to indicate whether or  
not the machine is switched on in an experiment. This value needs to be input at the  
initialization phase (1 = ON), (0 = OFF)

MACHINE .I(2) = A parameter used to indicate the number of stations loaded in a given instant of time. This variable is set at zero during the initialization phase.

If a machine has all its stations loaded it is taken from set IDLE, otherwise it remains in IDLE and BUSY. It is taken from BUSY only when no station is loaded.

4. CLASS TIME STATION . 24(5) BASED LOADED.2, UNLOADED.2

The entities 'STATION' represent the individual stations in the multiple stations machines. In the initialization of each experiment, 'STATIONS' numbers 1 to 12 are loaded into UNLOADED.1, meaning that they belong to MACHINE.1, while 'STATIONS' 13 to 24 are loaded into UNLOADED.2.

The attributes of each 'STATION' are:

STATION.I(1) = The identification number of the JOB which is loaded at the STATION

STATION.I(2) = Identification number of the mould which is mounted at the STATION

STATION.I(3) = A parameter used in order to cope with the changing value of 'process cycle time'. It keeps the value of the quantity still left to be produced from each JOB at a given point in time

STATION.I(4) = A parameter used to keep a time record related to the instant of times in which STATION.I(3) is measured

STATION.I(5) = A dummy parameter

Attributes STATION.I(1) and STATION.I(2) must be initialized. STATION.I(1) is set to zero and STATION.I(2) is set to the identification number of a mould. It is assumed that there is always a mould mounted in each station.

5. CLASS TIME STYLE.3(4) BSET POOLA

Entities STYLE represent individual product styles. Their time cells (T.STATION.I) are used to keep the value of arrival time of the next ORDER at the system. At the initialization period all entities STYLE are loaded at POOLA.

The attributes of STYLE are the following:

STYLE.I(1) = The number of product sizes in the product range

STYLE.I(2) = Total quantity to be demanded in the next customer order

STYLE.I(3) = Smallest product size in the product style range

STYLE.I(4) = Largest product size in the product style range

All four attributes must be initialized at the beginning. The values of STYLE.I(1) and STYLE.I(2) change during a run, while STYLE.I(3) and STYLE.I(4) are maintained constant. The time cells must also be initialized.

6. CLASS MOULD. 45(3) BSET PREE

Entities MOULD represent the moulds available in the system. If a MOULD is not mounted in a station, it is in 'PREE'. At the

beginning of each run all 'MOULDS' which are not mounted in a station must be loaded in 'PREE'. The three attributes of MOULD contain the code number of the product sizes which can be manufactured by that particular MOULD. A MOULD can be used in the manufacture of up to 3 different product styles. The values of the attributes are read as data at the beginning of each experiment.

A1 - 3.2 The input variables

1. NUEXP            Used to indicate the number of the experiment being conducted
2. PRIOR           Indicates whether to use subroutine \$ALLC or \$BLLC (PRIOR = 1, use \$ALLC; PRIOR = 0, use \$BLLC)
3. BOF             Used in conjunction with PRIOR, to indicate whether to use FIFO; FIFOB; FIFOM or FIFOMB priority rules, in accordance with the following table:

PRIOR	BOF	PRIORITY RULE
0	0	FIFO
0	1	FIFOB
1	0	FIFOM
1	1	FIFOMB

4. SOF             Used in conjunction with PRIOR to indicate whether to use SPT or SPTM rules. When SOF = 1, either SPT or SPTM is used depending on whether PRIOR is zero or one. When SOF = 1, BOF and SLACK must be set to zero.

5. SLACK                      Used in conjunction with PRIOR to indicate whether to use SLACK or SLACKM priority rules. When SLACK = 1, either SLACK or SLACKM are used depending on whether PRIOR is zero or one; when SLACK = 1, BOF and SOB must be zero.
6. EMPIRIC                  Controls whether to use empirical or theoretical distributions of interarrival times and demand. If EMPIRIC = 1, use empirical data; if EMPIRIC = 0, use theoretical distributions.
7. STATISTIC                Used to establish the length of the stabilization period for each run, which is measured by the number of completed orders
8. TSIMUL                   A dummy variable
9. STARPOINT                A dummy variable which was used to control the output of messages from the program. Its value is set in terms of simulation time units. If the simulation time is greater than STARPOINT the program outputs messages which are used as diagnostic information. It must be initialized with a large number (preferably above 4000 000), if the output is not desired.
10. NMOULD                  Indicates the number of moulds to be used in a particular experiment
11. NRUN                    Indicates the number of subdivisions if the run subdivision method of sampling is used. If independent runs is used, NRUN = 1
12. SZRUN                   Indicates the length of a run in terms of number of completed orders

- 13. TIRUN                      Indicates the number of replication runs.  
A pair of antithetic runs correspond to a value of 2 for TIRUN
- 14. NDAYS                     Indicates the number of working days per week.  
During the study NDAYS was set to five
- 15. NMACHB                    Indicates the number of machines defined in the program; NMACHB = 2
- 16. VCONV                     Indicates the number of minutes per working days
- 17. MAXLOT                    Used to set the value of the parameter for the splitting procedure. It indicates how large a job should be before it is split into smaller batches
- 18. NSTYL                     Indicates the number of product styles (NSTYL =3)
- 19. GENSTR                    A value used to initialize the different streams of random numbers for the different runs. If more than one submission for the same experiment is made, the difference between the values of GENSTR must be at least 100 to avoid repetition of the same stream
- 20. NIRUN                     Is a counter to control the number of independent runs. Used in connection with TIRUN.  
Initialized at 1
- 21. MXMOULD                  Indicates the maximum number of moulds defined in the program. MXMOULD = 45
- 22. IPARM (I)                Used to hold the values of any integer parameters of the theoretical probability distributions. It has a dimension of 20. In the present version of the program all values of IPARM = 0, as no integer parameters are used

23. PARM (I)      Used to hold the values of real parameters of the theoretical probability distributions.
- PARM (1) to PARM (3) hold the mean values of the interarrival times for each of the three product styles. The unit used for the interarrival times is hours. A typical value is 42.0 hours for the case of a load factor of 85%, the average size of order equals 1600, and 1 machine.
- PARM (4) to PARM (6) are dummy parameters and set to zero.
- PARM (7) to PARM (9) are used to keep the mean value of the distributions of order size. Typical values are 1600.0 and 1000.0
- PARM (10) to PARM (12) are dummy parameters and set at zero
- PARM (13) and PARM (14) are used respectively to store the values of the mean and standard deviation of the (normal) distribution of setup times. The unit used is minutes. Typical values used were 8.0 and 16.0 for mean values and 1.5 and 3.0 for standard deviation
- PARM (15) to PARM (20) are dummy parameters and set at zero.
24. CUSTARA (I,J), Are used to keep the values of the empirical distributions of interarrival times for each of the three product styles. All three distributions have a dimension (2, 9). The unit used is hours
- CUSTARB (I,J),
- CUSTARC (I,J)

25. VOLDA (I,J)  
VOLDB (I,J)  
VOLDC (I,J)
- Are used to keep the values of empirical distributions of order size for each of the three product styles. The dimension of all three distributions is (2,9)
26. MACSET (I,J)
- Is used to keep the values of the empirical distribution of setup times. The unit used is minutes. The dimension of variable is (2,7)
27. TDISA (I,J),  
TDISB (I,J),  
TDISC (I,J)
- Are used to keep the values of the empirical distributions of probabilities which are used to select the distributions of proportions of demand for the different product sizes in a range. Each array corresponds to a product style.
- Dimensions of each array is (2,4).(Used with empiric distributions)
28. RTYLA (I,J,K)
- Array used to keep the various distributions of proportions for each of the three product styles. Dimension is (3,3,15)
29. SSTYLA (I,J)
- A control variable used to indicate whether or not a particular product style should have its job split into smaller batches.Used in conjunction with MAXLOT. If SSTYLA (i,j) = 1, product style i, size j is considered for splitting, but if SSTYLA (i,j) = 0, then the product is never considered for splitting. Dimension of the array is (3,15)
30. STOCK (I,J)
- A control variable used to indicate whether or not a particular product size is kept in stock. If STOCK (i,j) = 1, product (i,j) is kept in stock. If STOCK (i,j) = 0, product (i,j) is not kept in stock. Dimension for this variable is (3,15)

31. RPOINT (I,J)    A variable used to keep the record of the reorder point for each one of the product sizes.  
Dimension is (3,15)
32. EBQ (I,J)       Variable used to keep the values of the 'replenishment orders' batch size, for each of the product styles. Dimension is (3, 15)
33. MOULD.I(J)      , Attributes of 'MOULD' relating to the product sizes it can manufacture. It has been defined already.  
Dimension (45, 3)
34. BCMACHINE(I)    Variable used to keep the value of the fixed part of the 'process cycle time' of the stations of a particular machine ( $BCMACHINE = N \times MC$  in equation 3.1 of paragraph 3.3.1, chapter 3).  
Dimension of BCMACHINE is (2)
35. FACHINE (I)     Variable used to keep the value of the variable part of the 'process cycle time' ( $FACHINE = 'I'$  in equation 3.1 of paragraph 3.3.1, chapter 3).  
Dimension of FACHINE (I) is (2)
36. RVOL (I,J)      A correction factor used to adjust the value of the order size in function of the pattern of demand (proportions) generated. Dimension of this variable is (3,3)
37. ARATE           A correction factor used to modify the interarrival time. It must be set to 1 as it is not used anymore
38. VRATE           A correction factor used to modify the value of size of orders. It must be set to 1 as it is not used anymore

39. PROCUM (I)      A Fortran variable used to store the probability distributions of the pattern of proportions for demand. It is used with the theoretical distributions of interarrival time and total quantity for demand. Dimensions of this variable is (14)
40. PERIOD          A variable used as a counter of the number of runs executed. It is initialized with a value zero
41. T.STYLE.I        A time cell used to keep the value of the next arrival of an order of style I. It is initialized with any value larger than zero. The unit used is minutes. The dimension of this variable is (3)
42. STYLA (I,J)      A variable used to store the values of the proportions that are required for each product size in a given order. It can be initialized with any of the patterns of proportions. Its dimension is (3,15)
43. STYLE.I(Z)       Represent the attributes of the entities CLASS TIME STYLE as defined before. It must be initialized at the beginning of each run to define the characteristics of the first order arriving at the shop for each product style. Dimension of this variable is (3,4)
44. QTSTCK (I,J)     Variable used to keep the record of stock level for each individual product size. It can be initialized with any desired positive value. The dimension of this variable is (3,15)
45. STATION.I(J)     Represent the attributes of the entities CLASS TIME STATION, as described before. Its dimension is (24,4) representing 4 attributes for each of the 24 sta-

tions. Only attributes 1 and 2 are initialized. STATION.I(1) is set to zero, indicating that no job is loaded at STATION.I and STATION.I(2) is set to the code number of different moulds. Each STATION.I(2) must be initialized with a unique code number

46. MACHINE.I(J) As described before this variable represent the attributes of the entities CLASS TIME MACHINE. The dimension of this variable is (2,2). MACHINE.I(1) must be initialized with 1 or zero to indicate respectively that the machine is switched-on or off in the experiment. MACHINE.I (2) is set to zero at the initialization or each run to indicate that none of the stations in the machine are loaded

A1 - 4 The flow charts

In the following pages five flow charts are presented. Figure A1 - 1 presents the flow chart for the procedure which is followed during the execution of pairs of antithetic runs in a single job submission. Figure A1 - 2 presents the flow chart of the main program MASTER MACH. Figure A1 - 3 presents the flow chart of the subroutine £ALLC. Figure A1 - 4 presents the flow chart of the subroutine £BLIC. Finally, figure A1 - 5 presents the flow chart of the subroutine £STCT.

APPENDIX 2

EMPIRICAL DATA USED IN THE PRELIMINARY INVESTIGATION

A2 - 1 Introduction

In this appendix the empirical data used in the preliminary investigation, and the cost data used in the study of strategies for capacity manipulation are presented. It should be pointed out that the distributions of interarrival times and order size, and the distribution of proportions are based on scarce data, as explained in paragraph 4.2. More comprehensive data was obtained later on but was not used in this preliminary investigation.

In the following tables the data used in the preliminary investigation is presented. Tables A2 - 1 to A2 - 3 present the distributions of interarrival times; tables A2 - 4 to A2 - 6 present the distributions of order sizes; tables A2- 7 to A2 - 9 present the distribution of proportions; table A2 - 10 presents the list of moulds, and table A2 - 11 presents the distribution of setup times.

The cost data used in the study of strategies for capacity manipulation is presented in table A2 - 12.

TABLE A2 - 1

DISTRIBUTION OF INTERARRIVAL TIMES

PRODUCT STYLE 1

Interarrival times (hours)	Cumulative distribution
18	0.1000
27	0.3000
45	0.4000
81	0.5000
117	0.6000
162	0.7000
171	0.8000
198	1.0000

$$\bar{X} = 104.4 \text{ hours}$$

TABLE A2 - 2

DISTRIBUTION OF INTERARRIVAL TIMES

PRODUCT STYLE 2

Interarrival times (hours)	Cumulative distribution
9	0.0714
27	0.2142
45	0.4285
54	0.6428
63	0.7857
72	0.8571
90	0.9285
117	1.0000

$$\bar{X} = 54.63$$

TABLE A2 - 3  
DISTRIBUTION OF INTERARRIVAL TIMES  
PRODUCT STYLE 3

Interarrival times (hours)	Cumulative distribution
4	0.3000
9	0.4000
27	0.5000
45	0.6000
63	0.7000
72	0.9000
81	1.0000
90	1.0000

$$\bar{X} = 36.90 \text{ hours}$$

TABLE A2 - 4  
DISTRIBUTION OF ORDERS SIZE  
PRODUCT STYLE 1

Demand category (class)	Cumulative distribution
500	0.1428
1500	0.2857
2500	0.4286
3500	0.5714
4500	0.7142
5500	0.8571
6500	1.0000
7500	1.0000

Although the mean value of this distribution is 3500, the actual value of the mean order size is 2404. This is because of the correction factors associated with the distribution of proportions (see table A2 - 7 for distribution of proportions).

TABLE A2 - 5

DISTRIBUTION OF ORDER SIZE

PRODUCT STYLE 2

Demand category (class)	Cumulative distribution
500	0.1111
1000	0.2222
1500	0.6667
2000	0.7778
2500	0.7778
3000	0.7778
3500	1.0000
4000	1.0000

Although the mean value of this distribution is 1833, the actual value for mean order size is 1971. This is because of the correction factors associated with the distribution of proportions. (See table A2 - 8 for distribution of proportions).

TABLE A2 - 6

DISTRIBUTION OF ORDER SIZE

PRODUCT STYLE 3

Demand category (class)	Cumulative distribution
900	0.1428
1450	0.2857
2000	0.4285
2600	0.5715
3150	0.8571
3700	0.8571
4300	1.0000
4900	1.0000

Although the mean value of this distribution is 2507, the actual value of the mean order size is 1611. This is because of the correction factors associated with the distribution of proportion. (See table A2 - 9 for distributions of proportions).

9	0.85
10	0.95
11	1.00

$$\bar{X} = 8 \text{ min.}$$

TABLE A 2- 12

Cost structure used in the study of strategies for capacity  
manipulation

Costs are given in a fictitious monetary unit called m.u.

1. Labour cost

Basic rate	- 3,942.00 m.u. for 40 hours/week
Next 4 hours/week (between 40 and 44 hours)	- premium of 25%
Next 4 hours/week (between 44 and 48 hours)	- premium of 50%
All after 48 hours/week	- premium of 100%

2. Cost of moulds

30,000.00 m.u. per mould with a depreciation period of 3 years.  
This means a depreciation rate of 10,000.00 m.u. a year.

3. Cost of machines

2,500,000.00 m.u. per machine with a depreciation period of 5  
years. This means a depreciation rate of 500,000.00 m.u. per year.

4. Inventory costs

Inventory is charged at 25% per year on the capital investment.  
The unit price of an item is equal to 10 m.u.. This means that  
inventory is charged at a rate of 2.5 m.u. per year/per item.

APPENDIX 3

DETAILS OF THE DISTRIBUTIONS OF PROPORTIONS AND GOODNESS-OF-FIT

TESTS ON THE EMPIRICAL DISTRIBUTIONS

A3 - 1 Details of the distribution of proportions.

The proportions of the total order which is required for each product size is called the distribution of proportions. The distribution used in the main core of the experiments was based on the distribution of proportions described in paragraph 2.2.3, and their numerical values are presented in the table below. It was assumed that all orders for all product styles would follow this distribution.

Product size	Proportions
2	0.003
2-1/2	0.004
3	0.043
3-1/2	0.055
4	0.122
4-1/2	0.133
5	0.169
5-1/2	0.139
6	0.149
6-1/2	0.078
7	0.076
7-1/2	0.026
8	0.021

A3 - 2 Goodness-of-fit tests on the empirical distributions

In order to decide on the distributions of interarrival times and order sizes a Kolmogoroff-Smirnof Goodness-of-fit test (1) was applied to the empirical data obtained in the industrial company. The analysis involves a much more comprehensive amount of data than the data used in the preliminary investigation. Four product styles are analysed where the first three correspond to the ones used in the preliminary investigation, and the fourth had been introduced after the first visit to the company. In the following tables the distributions of interarrival times and order sizes are tested against exponential distributions through the Kolmogoroff-Smirnof test.

(1) See SCHMIDT, J.W. and TAYLOR, R.E., 1970, Simulation and Analysis of Industrial Systems (USA, IRWIN INC.) p. 230

TABLE A3 - 1

DISTRIBUTION OF INTERARRIVAL TIMESPRODUCT STYLE 1 $\bar{X} = 7.05$  days

APPENDIX - 4

NUMERICAL RESULTS OF EXPERIMENTS WITH PRIORITY SCHEDULING RULES

#### A4 - 1 Introduction

As described in paragraph 6.1, the investigation with the priority scheduling rules consisted of thirty six experiments which were generated by testing each of six priority rules over six system configurations. Each one of the thirty six experiments was conducted in accordance with the sampling procedure described in paragraph 5.3.3, which means that six yields were generated for each one of the output variables.

Comparisons between the priority rules were made through the use of six measures of delivery performance, and five measures of internal behaviour. Four of the measures of delivery performance, viz. 'order late', 'tardiness of order', 'production late', and 'tardiness of production' were calculated for seven different values of the lead time D, meaning that 35 output variables were used, giving a total of 210 yields for every experiment. In tables 6.1 to 6.6 of chapter 6 the mean values and the result of the statistical tests for the six measures of delivery performance (for D = 8 days) were presented.

This appendix will present the mean values for all the five measures of internal behaviour (tables A4 - 1 to A4 - 6) and the mean values for the four measures of delivery performance which depend on the value of D, for D equal 8, 10, 12, 14, 16, 18 and 20. These values are the ones used in figures 6.1 to 6.24 of Chapter 6 and are presented here in tables A4 - 7 to A4 - 42.

In order to give an example of the procedure used in the statistical tests applied on the results of chapter 6, and to indicate the variability associated with the six yields obtained from the pair of antithetic runs, a selected example is presented in table A4 - 43.

$$MS_e = 0.307, \quad MS_{TR} = 0.720$$

$$F^*_{0.05} = 2.090 \quad F^*_{0.01} = 2.600$$

$$t^*_{0.05} = 2.350 \quad t^*_{0.01} = 3.110$$

$$FS = \frac{MS_{TR}}{MS_e} = \frac{0.720}{0.307} = 2.34 \quad \therefore FS > F^*_{0.01} \quad \text{hypothesis of equal mean is rejected}$$

$$D^*_{0.05} = t^*_{0.05} \sqrt{2MS_e/N} = 2.35 \cdot \sqrt{2 \cdot 0.307/6} = 0.75$$

$$D^*_{0.01} = t^*_{0.01} \sqrt{2MS_e/N} = 3.11 \cdot \sqrt{2 \cdot 0.307/6} = 0.99$$

(\*\*) The only rule significantly different is SPT

APPENDIX 5

MEAN VALUES OF YIELDS FROM INDIVIDUAL EXPERIMENTS IN THE

FACTORIAL DESIGN

A5 - 1 Introduction

As described in chapter 4, the factorial design consisted of 32 experiments. For each experiment 7 output variables were measured such that the main effects and interactions on these variables could be averaged over those 32 experiments. The results of the main effects and interactions have been already presented in chapter 7. In table A5 - 1, which follows, the 32 yields for each of the 7 output variables are presented.

FIGURE A5 - 1
