A STUDY OF HYBRID CONJUGATE

GRADIENT METHODS

by

Djamal Touati-Ahmed

A thesis submitted in partial fulfilment of the requirements for the award of

DOCTOR OF PHILOSOPHY

of the Loughborough University of Technology.

September 1989.

© by D. Touati-Ahmed 1989.

.

To: My wife PINA and my parents ZINA and EL-HABIB.

Acknowledgements

My sincere thanks are due to Professor C. Storey for his valuable supervision, guidance and comments for the research in this thesis.

I would also like to thank my wife Pina and my parents Zina and El-Habib for their great moral support.

Thanks are also due to Mrs. Wright for her patience while typing this thesis.

Finally I wish to thank the Algerian Ministry of Higher Education for sponsoring this research.

Summary

The main subject of the research in this thesis is the study of conjugate gradient methods for optimization and the development of improved algorithms. After an introductory first chapter, Chapter 2 contains a background of numerical methods for optimization in general and of conjugate gradient-type algorithms in particular. In Chapter 3 we study the convergence properties of conjugate gradient methods and discuss Powell's (1983) counter example that proves that there exist twice continuously differentiable functions with bounded level sets for which the Polak-Ribière method fails to achieve global convergence whereas the Fletcher-Reeves method is shown to be globally convergent, despite the fact that in numerical computations the Polak-Ribière method is far more efficient than that of Fletcher-Reeves. Chapters 4 and 5 deal with the development of a number of new hybrid algorithms, three of which are shown to satisfy the descent property at every iteration and achieve global convergence regardless of whether exact or inexact line searches are used. A new restarting procedure for conjugate gradient methods is also given that ensures a descent property to hold and global convergence for any conjugate gradient method using a non negative update. The application of these hybrid algorithms and that of the new restarting procedure to a wide class of well-known test problems is given and discussed in the final Chapter "Discussions and Conclusions". The results obtained, given in the appendices, show that a considerable improvement is achieved by these hybrids and by methods using the new restarting procedure over the existing conjugate gradient methods and also over quasi-Newton methods.

CHAPTER 1

1

INTRODUCTION

The research carried out in this thesis, concerns the study of numerical methods for optimization and the development of improved algorithms. This study is mainly concerned with the numerical methods for unconstrained optimization, for the simple reason that, as can be seen in Chapter 2, section 3, constrained problems in optimization can easily be converted into a sequence of unconstrained problems by a method of multipliers or into a sequence of unconstrained saddle points problems involving Lagrangians.

A particular interest is given to conjugate direction methods for optimization in general and to conjugate gradient-type algorithms in particular. This interest was triggered by a particular paper of Powell (1983) in that, although in numerical which he had shown computations, the conjugate gradient algorithm of Polak-Ribière (1969) is far more successful than that of Fletcher-Reeves (1964), if the Polak-Ribière algorithm is used, then even with exact arithmetic and exact line search, there exist twice continuously differentiable functions with bounded level sets, for which the gradient norms are bounded away from zero. In this same paper, Powell (1983) has also shown by a standard method of proof that the conjugate gradient algorithm of Fletcher-Reeves (1964) with exact arithmetic and exact line search is always convergent. This result has further been extended by Al-Baali (1985) to show that inexact line search satisfying some even with an standard conditions, the Fletcher-Reeves algorithm satisfies the descent property and is globally convergent.

After this introductory chapter, Chapter 2 of this thesis gives a thorough study of the theoretical and practical aspects of the existing numerical methods for optimization, providing an extensive literature survey of the subject and an up-to-date insight into these methods and their convergence properties. After the introductory section of Chapter 2, section 2 outlines and discusses the basic theorems and methods related to constrained optimization. In section3, we discuss and present the various techniques of converting constrained optimization problems into unconstrained optimization problems and solving these problems via unconstrained optimization. Section 4 deals with the numerical methods for unconstrained optimization. We discuss in this direct search and descent section both methods, outlining as much as possible, their convergence properties and the line search techniques. It will then be apparent how our interest was directed towards the methods of conjugate gradients, to which we have devoted the following section; section 5. In this latter section we go further in detail into the theoretical aspects of the conjugate gradient methods, from the generation of conjugate gradients in the case of quadratic functions, to the use of restarting (or reinitializing) in the case of general functions.

In Chapter 3, we discuss the computational efficiency and the convergence properties of conjugate gradient methods. This chapter is divided into four sections. introductory section containing all After an the preliminaries needed for the discussion of the following sections, section 2 deals will the descent properties and global convergence of the method of Fletcher Reeves. We prove the theorems given by Powell (1983) for the case of exact arithmetic and exact line search and the theorems given by Al-Baali (1985) for the case of inexact line search. The study then continues in section 3 by considering the method of Polak-Ribière that despite the fact that it is computationally far more efficient than that of Fletcher-Reeves, there exist twice continuously differentiable functions with bounded for which, if this method is used, level sets, the gradient norms remain bounded away from zero, meaning that the method fails to converge globally. In this section we give thorough computational comparisons based on both historical numerical results and on results the work included in this thesis. obtained from

Furthermore, we also attempt in this section to theoretically explain the reasons forthis feature of the Polak-Ribière method. We then conclude Chapter 3 by a fourth section dealing with the recent ideas in the literature to attempt to improve on the conjugate gradient methods and also ideas developed in this thesis in an attempt t_0 combine the desirable computational aspects of the Polak-Ribière method and the $vse \int u^{1/2}$ theoretical aspects of the Fletcher-Reeves method.

We then devote Chapters 4 and 5 of this thesis to the development of a number of new improved hybrid conjugate gradient algorithms. In Chapter 4, we develop two new algorithms and prove theorems for their descent properties and global convergence, whereas in Chapter 5, on top of providing a third globally convergent hybrid algorithm that proves to be even more efficient computationally than Quasi-Newton algorithms on a large class of test problems, we also give some new restarting criteria for conjugate

gradient methods, that provide descent property and global convergence for any conjugate gradient method with a non-negative update, and that prove to be computationally very efficient. The first two hybrids (HYBRID 1 and HYBRID 2) are also reported in Touati-Ahmed and Storey (1986) and the third hybrid (HYBRID 3) and the restarting criteria are reported in Touati-Ahmed and Storey (1987) which then has been communicated by L.C.W. Dixon to J.O.T.A. (Journal of Optimization Theory and Applications) and has been accepted for publication.

The discussions of the results obtained for the various methods dealt with in this thesis and their comparisons, together with our final conclusions are given in Chapter 6.

Chapter 2

Background of Numerical Methods

for Optimization

1. INTRODUCTION.

Numerical methods for optimization are designed to find an n-dimensional real vector $x^* \in K$ ($K \subset \mathbb{R}^n$) such that if $f : \mathbb{R}^n \to \mathbb{R}$ is the objective function to be minimized, we have:

$$f(x^{n}) \leq f(x)$$
 for all $x \in K$. (2.1.1)

A general optimization problem can be written in the following form:

Minimize f(x)

Subject to:

$$g_{i}(x) \leq 0 \qquad i = 1, 2, ..., m$$

$$h_{j}(x) = 0 \qquad j = 1, 2, ..., p \qquad (2.1.2)$$

where f, g_i and h_j are real valued functions from $\mathbb{R}^n \longrightarrow \mathbb{R}$. The set K of admissible (or feasible) points is written as follows:

$$K = \left\{ x \in \mathbb{R}^{n} \mid g_{i}(x) \leq 0, \quad i = 1, ..., m; \\ h_{j}(x) = 0, \quad j = 1, ..., p \right\}$$
(2.1.3)

By putting conditions on f, g_i , h_j and the set K, one can distinguish the existing problem type categories in optimization and develop numerical methods for solving each type of problem accordingly.

The particular case in which the functions f, g_i and h_j used in (2.1.2) are linear is termed "Linear Programming". To solve problems of this type, there exist good algorithms that always give an exact solution of the problem. For example, the Simplex method of Dantzig is a highly efficient algorithm. The average number of iterations required to reach an optimum for problems of n variables and m constraints with n much greater than m, is of the order 2m, much less than might be expected from the number of vertices of the constraint set. If a nonlinear programming problem can be arranged so as to be solvable by a modified simplex method, this is commonly the most efficient procedure. In particular, a problem which allows an adequate approximation by piecewise linear functions, of not too many variables, may be computed as a separable programming problem. Also a problem with a quadratic objective function and linear constrains can be solved by a modified simplex method, Such as the method of Wolfe.

Unless the problem is convex, any iterative method will, if it converges at all, converge to a local critical point, which is not necessarily the global optimum. This difficulty does not occur with a convex problem, for any local minimum of a convex problem is a global minimum. In general however, it is hard to find a computationally efficient algorithm which will always find the global minimum. There is always a tradeoff between efficiency, and the ability to follow small-scale features of the function. In practice, some assumption of smoothness of the function(s) is made. For further details on linear, quadratic, separable and convex programming the reader should refer to Zout endijk (1976), Fletcher (1981), Nimirovsky and Yudin (1983), Osborne (1985) and Minoux (1986) amongst others.

For the purpose of this thesis however, we shall distinguish

two main categories namely: Constrained and Unconstrained Optimization methods. Unconstrained optimization, as its name indicates, is the case in which there are no constraints g or h ; In other words the set K of admissible points is equal to \mathbb{R}^n . This is a very important case in practice because, as will be seen in Section 3 of this chapter, constrained problems in optimization can be converted into a sequence of minimum/maximum problems by a method of multipliers or into a sequence of saddle point problems using Lagrangians. Some of the recent text books dealing with unconstrained optimization include Wolfe (1978), Fletcher (1980), Gill, Murray and Wright (1981), Dennis and Schnobel (1983) and Minoux (1986). In the remaining part of this chapter, we shall give some basic results for constrained optimization, outline some of the methods with which constrained problems can be converted into unconstrained problems, give a description of some well known numerical methods for unconstrained optimization and give an explicit up-to-date study of conjugate gradient methods on which the research in this thesis is based.

2. SOME BASIC RESULTS FOR CONSTRAINED OPTIMIZATION.

The most important concept in the theory of constrained optimization is the concept of Lagrange multipliers. To illustrate the introduction of this concept, we shall first consider problem (2.1.2) with the equality constraints $h_j(x) = 0$, j = 1, ..., p only, that is we shall ignore the inequality constraints $g_i(x) \leq 0$, i = 1, ..., m for the time being. In this case the Lagrangian function takes the form:

$$\mathcal{L}(x,\lambda) = f(x) - \sum_{j=1}^{p} \lambda_{j} h_{j}(x)$$
 (2.2.1)

where λ_{j} , $j = 1, \ldots, p$ are the Lagrange multipliers of the constraints. The Lagrange multiplier of any constraint measures the rate of change in the objective function, consequent upon changes in that constraint function (see Fletcher (1981)). This information can be valuable in the sense that it indicates how sensitive the objective function is to changes in different constraints.

We now consider the additional complication of having inequality constraints as well as equality constraints. It is important to realize that only the active constraints at x^* (i.e. such that $g_i(x^*) = 0$) can influence the problem, but it is possible and consistent to regard any inactive constraint as having a zero Lagrange multiplier. The Lagrangian function takes therefore the form:

$$\mathfrak{L}(\mathbf{x},\lambda,\mu) = \mathbf{f}(\mathbf{x}) + \sum_{i=1}^{m} \lambda_{i} \mathbf{g}_{i}(\mathbf{x}) - \sum_{j=1}^{p} \mu_{j} \mathbf{h}_{j}(\mathbf{x})$$
(2.2.2)

where λ_i and μ_j are Lagrange multipliers of the constraints. For a more detailed study of the concept of Lagrange multipliers in optimization the reader should refer to Rockafeller (1976) and Fletcher (1981).

Having illustrated the introduction of Lagrange multipliers, we shall now discuss the optimality conditions and the existence and unicity of an optimal solution x^* of (2.1.2).

Since equality constraints can be converted into inequality constraints in the following manner:

$$h_{j}(\mathbf{x}) = 0 \iff \begin{cases} h_{j}(\mathbf{x}) \leq 0 \\ \text{and} \\ -h_{j}(\mathbf{x}) \leq 0 \end{cases}$$
(2.2.3)

it is no restriction to consider problem (2.1.2) with only inequality constraints. Therefore, in what follows, instead of (2.1.2), we shall consider the problem:

Minimize
$$f(x)$$

Subject to:
 $g_i(x) \leq 0$ $i = 1, ..., m$ (2.2.4)

We also make the general assumption that the functions f, g_1 , g_2 ,..., g_m are differentiable. For $x \in K$, let:

$$Z(\mathbf{x}) = \left\{ \mathbf{s} \in \mathbb{R}^{n} \mid \exists \ \overline{\alpha} > 0 \ \mathbf{s.t.} \ \mathbf{x} + \alpha \mathbf{s} \in \mathbf{K} \ \text{for} \ 0 \leq \alpha \leq \overline{\alpha} \right\}$$

be the set of feasible directions from x. A first optimality criterion via feasible directions is obtained by the following theorem.

<u>Theorem 2.2.1:</u> Let x^* be a feasible solution of the problem (2.2.4). If x^* is an optimal solution of (2.2.4) then we have:

$$s^{\mathrm{T}} \nabla f(x^{*}) \ge 0 \qquad \forall s \in \overline{Z(x^{*})}.$$
 (2.2.5)

If we strengthen our assumptions to impose the conditions that f is pseudoconvex (i.e. $(y-x)^T \nabla f(x) \ge 0 \Rightarrow f(y) \ge f(x)$), and that g_1, g_2, \dots, g_m are quasiconvex (i.e. $g_i(\lambda x + (1-\lambda)y) \le \max\{g_i(x), g_i(y)\}$ for $i = 1, \dots, m$) then we have:

$$x^*$$
 optimal $\Leftrightarrow s^T \nabla f(x^*) \ge 0 \quad \forall s \in \overline{Z(x^*)}$

The proof of this theorem is given in Appendix 1. This theorem gives necessary and sufficient conditions for a feasible point x^* to be optimal. Unfortunately these conditions are not very practical

in the sense that it is very difficult in practice to handle the set $Z(x^*)$. Fritz and John (1948) and Kuhn and Tucker (1951) give more practical conditions for a feasible solution to be optimal, using Lagrange multipliers and Lagrangian functions. For a more detailed study of these conditions, we also refer to Powell (1974), Avriel (1976), Fletcher (1981) and Minoux (1986).

In what follows we shall give some results concerning the existence and unicity of an optimal solution of problem (2.2.4), the proofs of which can be found in most text books dealing with constrained optimization.

Let

$$s(f,\alpha) = \left\{ x \in \mathbb{R}^n \mid f(x) \leq \alpha \right\}$$

be the level set of the function f at the level α .

Lemma 2.2.1: Suppose f is continuous. If there exists $x^{(0)} \in K$ for which $s(f,f(x^{(0)})) \cap K$ is compact then f has an optimal solution x^* in K.

Lemma 2.2.2: Suppose $f(x^{(k)}) \rightarrow \infty$ as $k \rightarrow \infty$ for all sequences $\{x^{(k)}\}_{k \in \mathbb{N}}$ from K such that $||x^{(k)}|| \rightarrow \infty$ as $k \rightarrow \infty$. Then we have: $s(f, f(x^{(0)})) \cap K$ is bounded.

<u>Theorem 2.2.2:</u> (Existence). Let f, g_1, \ldots, g_m be continuous functions and suppose the following condition is satisfied:

$$\left\{\left\{x^{(k)}\right\}_{k\in\mathbb{N}}\subset K; \|x^{(k)}\| \neq \infty\right\} \Rightarrow f(x^{(k)}) \neq \infty.$$

Then, the problem (2.2.4) has an optimal solution.

The proof of this theorem follows from Lemmas 2.2.1 and 2.2.2.

<u>Definition:</u> The Hessian matrix H(x) of f (the matrix of second derivatives of f at x) is said to be uniformly positive definite on a set $E \in \mathbb{R}^{n}$ if there exists m > 0 such that:

 $z^{T}H(x)z \ge m ||z||^{2} \quad \forall z \in \mathbb{R}^{n} \text{ and } \forall x \in E.$

Theorem 2.2.3: (Existence and Unicity).

. Let K be a closed convex set.

Let f be twice continuously differentiable in K, and

Let H(x) be uniformly positive definite on K.

Then:

f has a unique minimum x in K.

3. SOLVING CONSTRAINT OPTIMIZATION PROBLEMS VIA UNCONSTRAINED OPTIMIZATION.

Various methods have been suggested in the literature that enable constrained optimization problems to be solved via unconstrained optimization techniques. These methods solve the problem (2.2.4) by reducing the computational process to unconstrained minimization of a compound (or penalty) function, combining in a particular way the objective function f, the constraints g_1, \ldots, g_m and possibly one or more controlling parameters.

Surveying the literature in this subject, one can roughly distinguish three main classes of methods: The interior point methods: These methods operate in the set

$$\mathbb{R}^{\mathsf{o}} = \left\{ \mathbf{x} \in \mathbb{R}^{\mathsf{n}} \mid g_{\mathsf{i}}(\mathbf{x}) < 0 ; \quad \mathsf{i} = 1, \dots, \mathsf{m} \right\}.$$

The exterior point methods: These methods present an approach to a minimum solution x^* of the problem (2.2.4) from outside the constraints set:

$$\mathbf{R} = \left\{ \mathbf{x} \in \mathbb{R}^{n} \mid g_{\mathbf{i}}(\mathbf{x}) \leq 0, \quad \mathbf{i} = 1, \dots, m \right\}.$$

The Lagrangian methods: These methods are based on the Lagrangian function associated with problem (2.2.4) and they operate in the n-dimensional Euclidian vector space E.

The interior-point and exterior-point methods can be subdivided into two classes; the parametric methods have one or more controlling parameters in the penalty function to control the convergence towards a minimum solution; the non-parametric methods on the other hand, do not explicitly operate with controlling parameters. Lagrangian methods, however, are always parametric.

3.1 The Parametric Methods:

The parametric interior-point methods are based on penalty functions, which in this case are called "Barrier" functions, of the form:

$$B_{r}(x) = f(x) - r^{\lambda} \sum_{i=1}^{m} \Phi(g_{i}(x)) ,$$

where r denotes a positive controlling parameter, Φ is a function of one variable, n say, defined and continuously differentiable in the interval {n | n > 0} and such that $\Phi(0^+) = -\infty$, and

where λ denotes the order of the pole of Φ ' at $\eta = 0$. For further references on these methods we refer to Murray (1967), Davies (1970) and Lootsma (1972).

The parametric exterior-point methods on the other hand, are based on penalty functions, which in this case are called "Loss" functions, of the form:

$$L_{s}(x) = f(x) - s^{-\mu} \sum_{i=1}^{m} \psi(g_{i}(x)),$$

where s denotes a positive controlling parameter and ψ is a continuously differentiable function of one variable, η say, such that

$$\begin{split} \psi(\eta) &= 0 & \text{for } \eta \ge 0, \\ \psi(\eta) &< 0 & \text{for } \eta < 0. \end{split}$$

To define μ we need to introduce the function ω such that

$$\omega(\eta) = \psi(\eta) \quad \text{for } \eta \leq 0.$$

A loss function is then said to be of order μ if the derivative ω' of ω is analytic and if it has a zero of order μ at $\eta = 0$. Simple examples of loss functions are obtained by using $\omega'(\eta) = (-\eta)^{\mu}$ with positive integer μ . These methods were originated by Courant (1943). Further developments came from Ablow and Brigham (1955), Butler and Martin (1962), Fiacco and McCormick (1967a) and Beltrami (1969).

Mixed penalty functions were also considered in the literature so that many of the properties of barrier and loss function techniques can be established simultaneously. Combinations of these methods were first introduced by Fiacco and McCormick (1966). A mixed penalty function is given by:

$$M_{rs}(x) = f(x) - r^{\lambda} \sum_{i \in I_1} \Phi(g_i(x)) - s^{-\mu} \sum_{i \in I_2} \psi(g_i(x))$$

where $I_1 \cap I_2 = \phi$ and $I_1 \cup I_2 = I = \{1, 2, \dots, m\}$. This partitioning is arbitrary and either I_1 or I_2 may be empty.

3.2 The Non-Parametric Methods.

The non-parametric interior point methods are based on barrier functions of the form:

$$B_{t}(x) = p \phi(t-f(x)) + \sum_{i=1}^{m} \phi(g_{i}(x))$$

where t is a positive controling variable, \$\phi\$ is as defined for the parametric case and \$p\$ is a positive

weight factor attached to the term which contains the objective function to control convergence. An interesting development was initiated by Rosenbrock (1960a) and continued by Huard (1964) when he proposed the method of centres. It then has been theoretically and computationally explored by Faure and Huard (1965) and (1966), Bui Trong Lieu and Huard (1966), Huard (1967) and (1968) and Tremolières (1968). The method of centres generates a sequence of points converging to a minimum solution of the problem. Each of these points (or centres) is obtained by unconstrained maximization of a distance function: a particular combination of the objective function and the constraint functions. However, some distance functions may also be regarded as penalty functions without controlling parameters. Starting from this idea, Fiacco and McCormick (1967b) presented a non-parametric version of Sequential Unconstrained Minimization Techniques (S.U.M.T.), and Fiacco (1967) showed that similar versions can be obtained for a large class of interiorpoint as well as exterior-point methods.

The non-parametric exterior-point methods on the other hand, are based on loss functions of the form:

$$L_{t}(x) = p \psi(t-f(x)) + \sum_{i=1}^{m} \psi(g_{i}(x))$$

where ψ is as defined for the parametric case above and p as defined in the non-parametric interior-point case.

The unconstrained penalty functions turn out to be increasingly ill conditioned if the penalty parameter increases. Thus, the solution of the unconstrained optimization problems becomes more difficult. The numerical difficulties encountered, as reported in Murray (1967) and Lootsma (1969), stimulated further research. To overcome these difficulties, the use of some kind of scaling technique to the unconstrained problem seems to be a good remedy. For example, the algorithms presented in Fletcher (1970), Oren and Luenberger (1974) or Shanno and Phua (1978) could be applied. An alternative way is to prevent the occurrence of ill conditioned problems by the introduction of problems that do not suffer from this complication. This approach is done by means of "Augmented Lagrangian Functions".

3.3 The Lagrangian Methods:

Let us consider the classical constrained minimization problem:

The Lagrangian function to be considered is the following:

$$\mathfrak{L}(x,\lambda) = f(x) - \sum_{j=1}^{p} \lambda_{j} h_{j}(x)$$
 (2.3.2)

The stationary points of this function are characterized by the n+p nonlinear equations:

$$\nabla f(\mathbf{x}) - \sum_{j=1}^{p} \lambda_{j} \nabla h_{j}(\mathbf{x}) = 0$$

$$h_{j}(\mathbf{x}) = 0$$

$$\left. \right\}$$

$$(2.3.2)$$

with n+p variables $x_1, x_2, \dots, x_n, \lambda_1, \lambda_2, \dots, \lambda_p$. This technique of forming the Lagrange function (2.3.2) and solving the system (2.3.3) is called the Lagrange multiplier technique. By this method the dimensionality of the problem is considerably increased: the original problem (2.3.1) is a problem in E_n but the system (2.3.3) is a problem in E_{n+p} . However, more recent methods that reduce the solution of a constrained minimization problem to sequential minimization of a Lagrangian function as a function of x, exist. For further details in this subject the reader should refer to Fletcher (1969), Powell (1969), Lootsma (1972), Rockafeller (1974) and Van Der Hoek (1980).

4. NUMERICAL METHODS FOR UNCONSTRAINED OPTIMIZATION.

A particular interest is given to this and the next sections

of this chapter, for they represent the main area in which the research in this thesis has been undertaken. We shall first give a brief description of "Direct Search" methods, also known in the literature as "Ad-Hoc" methods, which will serve as an introduction to the development of "descent methods" on which the emphasis is to be placed.

4.1 Direct Search Methods.

The early direct search methods that were suggested for minimization are based on rough and ready ideas without much theoretical background. These methods only require the ability to evaluate the function at any given point and can be used for general continuous functions. In general however, they do not give a rapid rate of convergence and hence are inefficient for finding a minimum with high precision. There are nevertheless problems in which these features of an optimization method are not considered to be essential disadvantages.

If the problem is in only two or three dimensions, then it is possible that some sort of repeated bisection in each of the variables can be tried so as to establish a region in which the minimum lies. Then an attempt can be made to contract this region systematically. However, methods based on this sort of sectioning in n-dimensional problems have been suggested. A good review of this type of methods is given in Swann (1972).

Another possibility is to generate points $x^{(k)}$ at random in some fixed region, and select the one that gives the best function value over a large number of trials. Many variations of this random search idea have been suggested in the literature. See for example, Swann (1972).

One of the most reliable direct search methods is the "Simplex Method". This is not the simplex method for linear programming but its name is derived from the same geometrical concept. In this method we first determine the vertex at which the function value is smallest (largest if a maximum is being sought); then we form a new simplex by reflecting this vertex in the centroid of the other n vertices. The function is then evaluated at this new vertex and the process is repeated. This method was first introduced by Spendley et al. (1962) and then Nelder and Mead (1965) suggested a modified simplex method that allows irregular simplexes. Amongst other modifications of the simplex method, we find those of Box (1965), Ward, Nag and Dixon (1969) and Dambrauskas (1970) and (1972). Versions of this method to deal with constraints have also been suggested. There seemsto be a common belief at present that the Nelder and Mead variant of the simplex method is the most reliable direct search method in the presence of noise or error in the objective function and that it is reasonably efficient. Box and Draper (1969) stated that this algorithm is the most efficient of all current sequential techniques. For further details about these methods the reader should refer to Hans-Paul Schwefel (1981).

The "Alternative Variable Methods" form another class of direct search methods that operate as follows:- At iteration k, the kth component of the point $x^{(k)}$ (or the variable x_k) alone is changed in an attempt to reduce the function value, and the other

components are kept fixed. After the nth iteration, when all the variables have been changed, the whole cycle is repeated until convergence occurs. The strategy of Rosenbrock (1960b) of rotating coordinates and that of Hooke and Jeeves (1961) of pattern search belong to this class of methods. Further modifications have been proposed to the alternative variable methods, based on the observation that the points at the beginning and end of a cycle determine a line along which more substantial progress might be made. Thus, if provision is made for searching along this line (introduction to the idea of line searches), a more efficient method could result. The strategy of Davies, Swann and Campey (D.S.C.) that was originally described in Swann (1969), combines Rosenbrock's idea of rotating coordinates with one dimensional search methods, and the strategy of Powell (1964) of conjugate directions generates lines (or search directions) by joining up points in a similar way.

Versions of direct search methods that solve constrained problems are also available. For a full description of direct search methods, the reader should refer to Hans-Paul Schwefel (1981). Hans-Paul Schwefel (1981) together with Storey (1962) and Rosenbrock and Storey (1965) contain various examples of applications of direct search methods to both constrained and unconstrained optimization problems.

Descent methods that are described in the remaining part of this chapter, also generate search directions by joining up points in a similar way as described above, but have a stronger theoretical background and many of them have been developed to be more efficient.

Even when the gradient of the objective function and the solution of the one dimensional search problem are not computationally easily available, there exist very efficient numerical differentiation techniques and very efficient inexact line search procedures to overcome these difficulties. Therefore, the early direct search methods are gradually falling out of use, although in recent years there seems to be a new interest being given to these methods. The books of Hans-Paul Schwefel (1981) and Reklaitis, Ravindran and Ragsdell (1983) are a result of this recent interest.

4.2 Descent Methods.

We shall now consider methods that in addition to using function values also make use of the gradient of the objective function. Descent methods form a class of methods in which the solution of the general unconstrained minimization problem:

$$Min f(x) , x \in \mathbb{R}^{n}$$
 (2.4.1)

is found by solving a sequence of one dimensional problems. The conjugate direction methods are generally the most important descent methods for solving the general unconstrained minimization problem (2.4.1), from the point of view of practical computations. They assume that in the neighbourhood of the minimum, the function can be closely approximated by a positive definite quadratic form, and this is the major assumption made in the development of descent methods in general.

In the application of descent methods, the following situation is typical. We attempt to move from the current point $x^{(k)}$ in such a way as to reduce the value of the objective function f. Each

descent method is characterized by the provision of a descent vector $s^{(k)}$ at each iteration k (Search Direction), and the next point, $x^{(k+1)}$, is found by solving the one dimensional minimum problem, in which the function to be minimized is:

$$\Phi(\alpha) = f(x^{(k)} + \alpha s^{(k)}) . \qquad (2.4.2)$$

Geometrically, we proceed in the direction $s^{(k)}$ to lower and lower level surfaces until $x^{(k+1)}$ is reached. As we cannot further reduce f in this direction, $s^{(k)}$ must lie in the tangent plane to the level surface through $x^{(k+1)}$. Therefore we have:

$$s^{(k)^{1}}g^{(k+1)} = 0$$
 (2.4.3)

where $g^{(k+1)} = \nabla f(x^{(k+1)})$ denotes the gradient of f at $x^{(k+1)}$. This situation is sketched in Figure 2.4.1 below:

Figure 2.4.1 : The descent vector $s^{(k)}$ lies in the tangent plane to the level surface through $x^{(k+1)}$.

At iteration k of a descent method, the following property is satisfied:

$$s^{(k)} g^{(k)} < 0$$
 (2.4.4)

This property (2.4.4) is called the descent property and s^(k) is said to be a descent (or downhill) vector.

In descent methods, the descent vector $s^{(k)}$ is usually a certain transformation of the gradient of f at $x^{(k)}$: $g^{(k)}$. That is to say that all descent methods use the basic iterative step:

$$x^{(k+1)} = x^{(k)} + \alpha Bg^{(k)}$$
(2.4.5)

where B is a matrix defining a transformation of the gradient and α is the step length in the direction $s^{(k)} = B.g^{(k)}$. The important question that arises at this stage is how to choose a "good" direction $s^{(k)}$, in other words how to choose a suitable transformation matrix B of the gradient $g^{(k)}$. In contrast to the one-dimensional case, where the only moves are in the positive or negative directions, even in two dimensions there are an infinite number of possible choices. In what follows we shall describe different methods for specifying $s^{(k)}$ and how to choose a suitable step length α to ensure a sufficient decrease in the function value. A descent method is usually named according to the procedure by which it computes the search direction, since the determination of the step length α is common to all descent methods and is usually viewed as a separate procedure (Line Search Procedure).

Before considering specific algorithms however, we shall first consider some necessary and sufficient conditions for the convergence of descent methods.

4.2.1 Convergence Theorems For Descent Methods.

The study of convergence for descent methods can be made considerably easier by considering a model algorithm. This will make it possible to carry out crucial reasoning in establishing the convergence of an algorithm, without becoming submerged in the clutter that is otherwise introduced by the great complexity of the subroutines used in modern algorithms. All descent methods have the basic general form of the model algorithm below:

- The Model Algorithm For Descent Methods:-
 - Step 1 : If the convergence conditions are satisfied the algorithm terminates with the current point $x^{(k)}$ as the solution.

Step 2 : Compute a descent search direction $s^{(k)} \neq 0$.

- Step 3 : Compute a step length $\alpha^{(k)} > 0$ satisfying $f(x^{(k)} + \alpha^{(k)} s^{(k)}) < f(x^{(k)})$.
- Step 4 : $x^{(k+1)} = x^{(k)} + \alpha^{(k)} s^{(k)}$, k = k+1 and go to Step 1.

Because the search direction $s^{(k)}$ computed in Step 2 is a descent direction, it follows that there must exist $\alpha > 0$ such that $f(x^{(k)} + \alpha s^{(k)}) < f(x^{(k)})$. The requirement that $f(x^{(k+1)}) < f(x^{(k)})$ is not sufficient to ensure that the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$ converges to a minimum of f. Ideally $\alpha^{(k)}$ is chosen to solve the onedimensional minimization problem

Min
$$f(x^{(k)} + \alpha s^{(k)}), \quad \alpha \in \mathbb{R}^+ - \{0\}$$
, (2.4.6)

but in practice however, an exact solution to problem (2.4.6)

is not usually possible and one accepts any value of $\alpha^{(k)}$ that satisfies certain standard conditions. The concept of exact and inexact line searches is investigated in subsection 4.2.2 below.

Let $x^{(1)}$ be an arbitrary starting point for a descent method of the form of the model algorithm above to solve the problem (2.4.1). The level set for this problem is therefore defined as follows:

$$\left\{ x \in \mathbb{R}^{n} : f(x) \leq f(x^{(1)}) \right\} \qquad (2.4.7)$$

We also introduce:

$$\cos(\theta^{(k)}) = -\frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\| \cdot \|s^{(k)}\|} , \qquad (2.4.8)$$

where $\theta^{(k)}$ is the angle between the negative gradient $-g^{(k)}$ and the search direction $s^{(k)}$. For all descent methods $\cos(\theta^{(k)}) > 0$ holds. We now establish the following convergence theorem.

Theorem 2.4.1 (Zoutendijk (1976)).

Suppose continuously (1) f is twice differentiable in (2.4.7);

- (2) (2.4.7) is bounded;
- (3) The Hessian matrix H(x) of second partial derivatives of f is bounded in (2.4.7);
- (4) $\alpha^{(k)} = \operatorname{Arg Min}_{\alpha>0} f(x^{(k)} + \alpha s^{(k)})$
- (5) $\Sigma_k \cos^2(\theta^{(k)}) = + \infty$.

Then $\nabla f(\overline{x}) = 0$ for at least one point of accumulation \overline{x} of the sequence $\{x^{(k)}\}$ generated by the model algorithm.
Theorem 2.4.2 (Zoutendijk (1976)).

If in Theorem (2.4.1) we replace condition (5) by the following condition:

(5') $\exists k' \in \mathbb{N}$ and $\exists \theta > 0 : \forall k \ge k' \cos(\theta^{(k)}) \ge \theta > 0$, then $\forall f(\overline{x}) = 0$ for all points of accumulation \overline{x} of the sequence $\{x^{(k)}\}$ generated by the model algorithm.

Proofs of Theorems 2.4.1 and 2.4.2.

Let us first consider the proof of Theorem 2.4.1. Suppose that for all points of accumulation \overline{x} of the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$ generated by the model algorithm above, we have $\nabla f(\overline{x}) \neq 0$. Then there exists a constant ε say, such that:

$$\|\nabla f(\mathbf{x}^{(k)})\| \ge \varepsilon > 0 \qquad \text{for all } k \qquad (2.4.9)$$

It is no restriction and no loss of generality to assume that $\|s^{(k)}\| = 1$. Let $\mu^{(k)}$ be the first value of α such that

$$\nabla f(x^{(k)} + \mu^{(k)}s^{(k)})^{T}s^{(k)} = \frac{1}{2} \nabla f(x^{(k)})^{T}s^{(k)}$$
 (2.4.10)

Hence $0 < \mu^{(k)} < \alpha^{(k)}$. Now, if Ω is an upper bound on $\|\nabla^2 f(x)\|$, where x is any point in the level set (2.4.7), then we have

$$\nabla f(x^{(k)} + \mu^{(k)}s^{(k)})^{T}s^{(k)} \leq \nabla f(x^{(k)})^{T}s^{(k)} + \Omega \mu^{(k)} \|s^{(k)}\|^{2}$$
. (2.4.11)

Therefore using (2.4.10) and the assumption that $||s^{(k)}|| = 1$, we obtain:

$$\mu^{(k)} \ge - \frac{\nabla f(x^{(k)})^{T} s^{(k)}}{2\Omega} \qquad (2.4.12)$$

Now, we also have:

$$f(x^{(k)} + \mu^{(k)}s^{(k)}) = f(x^{(k)}) + \mu^{(k)} \nabla f(x^{(k)} + \lambda \mu^{(k)}s^{(k)})^{T}s^{(k)}$$
(2.4.13)

where $0 \le \lambda \le 1$. But $f(x^{(k+1)}) = f(x^{(k)} + \alpha^{(k)}s^{(k)}) < f(x^{(k)} + \mu^{(k)}s^{(k)})$, and therefore we have:

$$f(x^{(k)}) - f(x^{(k+1)}) > f(x^{(k)}) - f(x^{(k)} + \mu^{(k)}s^{(k)})$$
$$= -\mu^{(k)} \nabla f(x^{(k)} + \lambda \mu^{(k)}s^{(k)})^{T}s^{(k)}$$

Now, because $\lambda \leq 1 \Rightarrow \lambda \mu^{(k)} \leq \mu^{(k)}$ and therefore:

$$-\nabla f(x^{(k)} + \lambda \mu^{(k)} S^{(k)})^{T} s^{(k)} \leq \nabla f(x^{(k)} + \mu^{(k)} s^{(k)})^{T} s^{(k)}$$
(2.4.14)

And therefore using (2.4.12) and (2.4.14) we obtain:

$$f(x^{(k)}) - f(x^{(k+1)}) > \frac{1}{2\Omega} \nabla f(x^{(k)})^{T} s^{(k)} \cdot \nabla f(x^{(k)} + \mu^{(k)} s^{(k)})^{T} s^{(k)} .$$
(2.4.15)

By substituting (2.4.10) and (2.4.8) into (2.4.15) we obtain:

$$f(x^{(k)}) - f(x^{(k+1)}) > \frac{1}{4\Omega} \cos^2(\theta^{(k)}) \|\nabla f(x^{(k)})\|^2$$

and finally by using (2.4.9) we get:

$$f(x^{(k)}) - f(x^{(k+1)}) > \frac{\epsilon^2 \cos^2(\theta^{(k)})}{4\Omega}$$

Since $\Sigma_k \cos^2(\theta^{(k)}) = \infty$, it follows that $\Sigma_k \left\{ f(x^{(k)}) - f(x^{(k+1)}) \right\} = \infty$ which is impossible because $x^{(k)}$ is in the bounded level set (2.4.7). Hence, for at least one point of accumulation \overline{x} of the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$ generated by the model algorithm above we have $\nabla f(\overline{x}) = 0$.

Let us now assume that condition (5) of Theorem 2.4.1 is replaced by condition (5') of Theorem 2.4.2 and prove Theorem 2.4.2.

(k₂) Let \overline{x} be a point of accumulation and $\{x\}$ $_{l\in\mathbb{N}}$, a subsequence of the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$, converging to \overline{x} . Suppose there exists $\epsilon > 0$ such that (2.4.9) is true for all k. Therefore for a sufficiently large $\ell \in \mathbb{N}$ we have:

$$\|\nabla f(x^{(k_{\ell})})\| \geq \frac{1}{2} \varepsilon.$$

Let $k_{\ell} \ge k'$ (k' sufficiently large). It then follows from the proof of Theorem (2.4.1) that:

$$f(x^{(k_{\ell})}) - f(x^{(k_{\ell}+1)}) \ge \frac{(\nabla f(x^{(k_{\ell})})^{T_{s}})^{(k_{\ell})}}{4\Omega}$$
$$= \frac{\cos^{2}(\theta^{(k_{\ell})}) \|\nabla f(x^{(k_{\ell})})\|^{2}}{4\Omega}$$
$$\ge \frac{\theta^{2} \varepsilon^{2}}{16\Omega} \quad .$$

H

ence
$$\Sigma_k \left\{ f(x^{(k_l)}) - f(x^{(k_l+1)}) \right\} = \infty$$
 which is again impossible

for the same reason as above.

The conditions for Theorem 2.4.1 to hold are quite reasonable. The second condition prevents infinite solutions and in particular convergence of $f(x^{(k)})$ to a finite value while $x^{(k)} \rightarrow \pm \infty$. This will exclude functions such as ex that are bounded below but strictly decreasing as x becomes infinite. The third condition, that can only be eligible to hold if the first condition holds, puts a restriction on the curvature of the objective function. It can be expected that functions with unbounded second partial derivatives

will present special problems. We shall not comment on the fourth condition at this stage since a full investigation on how to compute the step lengths $\alpha^{(k)}$ is given in the following subsection 4.2.2. Finally, the fifth condition states that the angle between the negative gradient and the search direction should not go to $\pi/2$ too rapidly. This is strengthened in Theorem 2.4.2. There must be a limit on the closeness of $s^{(k)}$ to orthogonality to the negative eradient. This prevents s^(k) to be chosen so that to first order, f is almost constant along $s^{(k)}$ which will only occur if $s^{(k)}$ is almost parallel to the first-order approximation to the contour line $f(x) = f(x^{(k)})$, so that the negative gradient and the search direction are almost orthogonal (i.e. - $\nabla f(x^{(k)})^T s^{(k)} / | \nabla f(x^{(k)}) || s^{(k)} ||$ is close to zero). The stronger requirement (5') implies strong convergence $(\nabla f(\overline{x}) = 0$ for all points of accumulation); condition (5) only implies weak convergence (there exists a point of accumulation \overline{x} with $\nabla f(\overline{x}) = 0$). If there is only one point of accumulation, which is usually the case in practice, then it does not make any difference; if there is more than one point of accumulation, then they obviously all have the same value.

The type of convergence result, that has just been established, is termed "Global Convergence", since there is no restriction on the closeness of $x^{(1)}$ to a stationary point. For further details on the study of global convergence we refer to Ostrowski (1966), Wolfe (1969), Sargent and Sebastian (1973), Polak, Sargent and Sebastian (1974), Zoutendijk (1970) and (1976), Fletcher (1980) and Gill, Murray and Wright (1981). 30

Even when it can be proved theoretically that a sequence $\{x^{(k)}\}_{k\in\mathbb{N}}$ generated by the model algorithm above will converge in the limit to the required minimum, a method will be practicable only if convergence occurs with some rapidity. Global convergence, however, does not give a measure of this rapidity and hence gives practically no idea on how efficient the method is. In what follows we shall briefly discuss some means of characterizing the rate of convergence at which such sequences converge.

Let $\{x^{(k)}\}_{k\in\mathbb{N}}$ be a sequence of points generated by the model algorithm above, converging to x^* . To simplify the discussion, we shall assume that the elements of this sequence are distinct, and that for no value of k does $x^{(k)}$ equal x^* .

An effective technique for judging the rate of convergence is to compare the improvements at two consecutive steps, i.e., to measure the closeness of $x^{(k+1)}$ to x^* relative to that of $x^{(k)}$ to x^* .

A sequence of $\{x^{(k)}\}_{k\in\mathbb{N}}$ is said to converge with order r, if r is the largest number such that

$$0 \leq \overline{\lim_{k \to \infty}} \frac{\|x^{(k+1)} - x^*\|}{\|x^{(k)} - x^*\|^{r}} < \infty$$
(2.4.16)

r is usually known as the asymptotic rate of convergence. If r = 1, the sequence is said to have linear convergence and if r = 2, it is said to have quadratic convergence.

If the sequence $\{x^{(k)}\}_{k\in\mathbb{N}}$ has order of convergence r, the asymptotic error constant is the value γ that satisfies:

$$\gamma = \frac{1}{\lim_{k \to \infty}} \frac{\|x^{(k+1)} - x^*\|}{\|x^{(k)} - x^*\|^r} .$$
(2.4.17)

When r = 1, γ must be strictly less than 1 in order for convergence to occur.

If a sequence has linear convergence, the step-wise decrease in $||x^{(k)} - x^*||$ varies substantially with the value of the asymptotic error constant. If the latter is zero when r = 1, the associated type of convergence is given the name superlinear convergence. Note however, that any value of r greater than 1 implies superlinear convergence. For more detailed studies of rates of convergence we refer to Polak (1971), Wolfe (1978) and Gill, Murray and Wright (1981).

4.2.2 Line Search Techniques.

Until the mid sixties, the prevailing belief was that the step lengths $\alpha^{(k)}$ should be chosen to solve the one-dimensional minimization problem:

$$\begin{array}{ll}
\operatorname{Min} & \Phi(\alpha) \\
\alpha > 0
\end{array} (2.4.18)$$

accurately, where Φ is as defined in (2.4.2). However, more careful computational testing has led to a turnabout. In this subsection we shall describe some of the techniques that only impose some weak acceptance criteria on $\alpha^{(k)}$, that lead to methods that perform as well in theory and better in practice.

In the proof of Theorem (2.4.1), we defined $\mu^{(k)}$ as the first value of α such that (2.4.10) holds. $\mu^{(k)}$ can also be defined by

$$\nabla f(x^{(k)} + \mu^{(k)}s^{(k)})^{T}s^{(k)} = \sigma \nabla f(x^{(k)})^{T}s^{(k)},$$

where $0 < \sigma < 1$. In this case we have:

 $\mu^{(\mathbf{k})} \geq -\frac{1-\sigma}{\Omega} \cos(\theta^{(\mathbf{k})}) \cdot \| \nabla f(\mathbf{x}^{(\mathbf{k})}) \|$

It then follows that convergence can still be maintained even if we do not require $\alpha^{(k)}$ to be the solution of the one-dimensional minimization problem (2.4.18) but only require that $\alpha^{(k)} \ge \mu^{(k)}$. Hence, if during the line search an α is found with:

$$\nabla f(x^{(k)} + \alpha s^{(k)})^{T} s^{(k)} \ge \sigma \nabla f(x^{(k)})^{T} s^{(k)}$$
 (2.4.19)

we may stop the search for α .

A frequently used method for determining the step lengths $\alpha^{(k)}$ is to estimate a local minimizer of $\Phi(\alpha)$. Then $\alpha^{(k)}$ satisfies at least approximately the requirement:

$$\alpha^{(k)} = \operatorname{Arg} \min_{\alpha > 0} f(x^{(k)} + \alpha s^{(k)}) . \qquad (2.4.20)$$

In other words, $\alpha^{(k)}$ satisfies at least approximately the requirement:

$$\Phi^{*}(\alpha) = 0, \qquad (2.4.21)$$

where Φ' is the first derivative of Φ .

In general (2.4.21) is a nonlinear equation and so it cannot usually be solved analytically. Therefore a numerical method for estimating a value of α that satisfies (2.4.21) must be used. When $\alpha^{(k)}$ is chosen to satisfy (2.4.20) accurately, the procedure is termed an "Exact Line Search" and when (2.4.20) is only satisfied approximately, the procedure is termed an "Inexact Line Search".

A fundamental requirement for a step length algorithm associated with a descent method involves the change in f at each iteration. If convergence is to be assured, the step length must produce a "Sufficient" or "Satisfactory" decrease in f(x). Although it seems to be common sense to require that:

$$f(x^{k+1}) < f(x^{(k)})$$
,

it comes as no great surprise that this simple condition does not guarantee that the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$ will converge to a minimizer of f. Simple counter examples to prove this statement can be found in most good text books dealing with line searches and step lengths. For example see Gill, Murray and Wright (1981) and Dennis and Schmabel (1983).

The "Sufficient" or "Satisfactory" decrease in f(x) requirement is usually satisfied by several alternative sets of conditions on $\alpha^{(k)}$. Although the process of finding $\alpha^{(k)}$ by estimating a minimizer of Φ produces a satisfactory decrease in the value of f at each iteration of a descent algorithm, the line search is computationally expensive, in that several evaluations of f or ∇f are required; in fact the major part of the computational labour required to implement many descent algorithms is that required to determine $\alpha^{(k)}$. The computational efficiency of the line search therefore usually determines the computational efficiency of the whole descent algorithm. Consequently a great deal of effort has been expended upon the construction of efficient line search procedures. Most of these procedures are based on the principles of Goldstein (1962), (1965) and (1967) and Armijo (1966) from which the well known Goldstein-Armijo principle is derived.

The Goldstein-Armijo principle is as follows: A sufficient decrease in f(x) is achieved if $\alpha^{(k)}$ satisfies:

$$\alpha^{(k)} q_{2} \nabla f(x^{(k)})^{T} s^{(k)} \leq f(x^{(k+1)}) - f(x^{(k)}) \leq \alpha^{(k)} q_{1} \nabla f(x^{(k)})^{T} s^{(k)}$$

$$(2.4.23)$$

34

(2.4.22)

where q_1 and q_2 are scalars satisfying $0 < q_1 < q_2 < 1$ and $q_1 = 1 - q_2$. The upper and lower bounds of (2.4.23) ensure that $\alpha^{(k)}$ is neither too large nor too small.

In typical algorithms based on (2.4.23), the trial values of the step length are defined in terms of an initial step $\alpha^{(1)}$ and a scalar ω . The value of $\alpha^{(k)}$ is taken as the first member of the sequence $\{\omega^{j} \alpha^{(1)}\}$, j = 0, 1, ..., for which (2.4.23) is satisfied for some q_1 and q_2 .

The performance of these algorithms depends critically on the choice of $\alpha^{(1)}$, rather than on any merits of condition (2.4.23). Step length algorithms of this type perform well only for descent methods in which an a priori value of $\alpha^{(1)}$ tends to be a good step, so that only the first member of the sequence $\{\omega^j \alpha^{(1)}\}$ usually needs to be computed. We must emphasize however, that condition (2.4.23) alone does not guarantee a good value of $\alpha^{(k)}$. Although this strategy would be "efficient" in that a suitable $\alpha^{(k)}$ would be found with only a single function evaluation per iteration, any descent method that uses such a step length algorithm would be extremely inefficient. It is important, for the sake of the computational labour required, to minimize the number of function evaluations, but it is also essential to consider the performance of a step length algorithm not merely in terms of that, but also in terms of the overall reduction in f achieved at each step.

Obviously there is a tradeoff between the effort expended to determine a good $\alpha^{(k)}$ at each iteration and the resulting benefits for the descent method. The balance varies with the type of algorithm as well as the problem to be solved, and hence some

35

flexibility is desirable in specifying the conditions to be satisfied by $\alpha^{(k)}$.

Fletcher (1980) suggests that $\alpha^{(k)}$ is such that $x^{(k+1)}$ satisfies the condition:

$$|g^{(k+1)^{T}}s^{(k)}| \leq -\sigma g^{(k)^{T}}s^{(k)},$$
 (2.4.24)

together with the Goldstein (1965) requirement that:

$$f(x^{(k+1)}) \leq f(x^{(k)}) + \rho \alpha^{(k)} g^{(k)} s^{(k)}$$
 (2.4.25)

where $g^{(k)} = \nabla f(x^{(k)})$ is the gradient vector at $x^{(k)}$, and where $\rho \in (0, \frac{1}{2})$, $\sigma \in (0, 1)$ and $\rho < \sigma$.

Condition (2.4.24) ensures that $\alpha^{(k)}$ is not too small. The value of σ determines the accuracy with which $\alpha^{(k)}$ approximates a stationary point of f along s^(k), and consequently provides a means of controlling the balance of effort to be expended in computing $\alpha^{(k)}$. The case of exact line search occurs when $\sigma = 0$, condition (2.4.25) requires that $f(x^{(k)} + \alpha s^{(k)})$ lies on or below the line $\ell(\alpha) = f(x^{(k)}) + \rho \propto g^{(k)} s^{(k)}$, and ensures a sufficient decrease when used together with (2.4.24).

An advantage of condition (2.4.24) as an acceptance criterion is that its interpretation in terms of a local minimizer suggests efficient methods for computing a good value of $\alpha^{(k)}$. In particular safeguarded polynomial fitting techniques for univariate minimization converge very rapidly on well behaved functions. A full description of these techniques can be found in Gill, Murray and Wright (1981).

A similar procedure is described in Dennis and Schnabel(1983). They give an algorithm of backtracking line search procedure using quadratic and cubic interpolation.

One of the most recent investigations of line search procedures, is due to Al-Baali and Fletcher (1986). Their investigation is mainly aimed at developing a line search method that is applicable to the nonlinear least-squares problem in which f(x) is a sum of squares of nonlinear functions:

$$f(x) = \frac{1}{2} \sum_{i=1}^{m} (r_i(x))^2 . \qquad (2.4.26)$$

If $r \in \mathbb{R}^{m}$ denotes the column vector whose elements are the functions $r_{i}(x)$ and $A = \nabla r^{T}$ is the Jacobian matrix of r, then it follows that:

$$g(x) = A(x).r(x)$$
 (2.4.27)

Thus, to evaluate f(x) requires an evaluation of r(x), and to evaluate g(x) requires in addition an evaluation of the Jacobian matrix.

Their work consisted of a study of various iterative schemes for the line search sub-problem that guarantee finding an acceptable step length α in a finite number of steps. This is achieved by first bracketing an interval of acceptable α values, and then reducing this bracket uniformly by repeated sectioning the bracket in a systematic way. These schemes for the line search sub-problem include a scheme for finding an acceptable value of α that satisfies (2.4.19) together with the Goldstein (1965) requirement (2.4.25). This is then generalized to find an acceptable value of α that satisfies (2.4.21) and (2.4.25) * that of Fletcher (1980). Further modifications were also suggested with the aim of producing

* as well as

schemes in which the gradient vector is evaluated as infrequently as possible, on the assumption that this is the major cost in using the methods.

Their work shows in particular that substantial gains in efficiency can be obtained in nonlinear least-squares problems by making polynomial approximations to the individual functions r_i , rather than the overall function f of (2.4.26).

For more details on line search techniques, we refer to Wolfe (1978), Fletcher (1980), Gill, Murray and Wright (1981) and Dennis and Schnabel (1983).

Having established some convergence results and described some line search techniques for descent methods, we are now left with the question of how to choose a suitable descent direction of search s^(k). As mentioned earlier, a descent method is usually named according to the procedure by which it computes the search direction. Therefore, describing a procedure for determining a search direction is in fact describing a specific descent method. Some of these methods are described below.

4.2.3 The Method of Steepest Descent.

One of the oldest and simplest methods for finding a solution to the general minimization problem (2.4.1) is the method of steepest descent. This method was originally proposed by Cauchy (1847) for the solution of systems of nonlinear equations.

Consider the linear approximation to f based on the Taylor series expansion about $x^{(k)}$:

38

$$f(x^{(k)} + s) \approx f(x^{(k)}) + g^{(k)^{T}}.s$$
 (2.4.28)

Assuming that a step of unity will be taken along s, it would appear that a good way to achieve a large reduction in f(x) is to choose s so that $g^{(k)}^{T}$ s is large and negative. Obviously some normalization must be imposed on s, otherwise, for any \overline{s} such that $g^{(k)}^{T} \overline{s} < 0$, one would simply choose s as an arbitrary large positive multiple of \overline{s} . The aim, however, is to choose s so that, amongst all suitably normalized vectors, $g^{(k)}^{T}$ s is minimum.

Given some norm $\|\cdot\|$, s^(k) is thus the solution of the minimization problem:

$$\begin{array}{l} \operatorname{Min} \quad \frac{g^{\left(k\right)^{1}} s}{s \in \mathbb{R}^{n}} \quad . \qquad (2.4.29) \\ \end{array}$$

The solution of the problem (2.4.29) depends on the choice of norm. When the norm is defined by a given symmetric positive definite matrix, C say, (i.e. $\|s\|_{C} = (s^{T}C s)^{\frac{1}{2}}$, the solution of (2.4.29) is:

$$s^{(k)} = -C^{-1}g^{(k)}$$
 (2.4.30)

The matrix B defined in (2.4.5) used as a transformation of the gradient is in this case

$$B = -C^{-1}$$

If the two-norm is used, (i.e. $s = (s^T s)^{\frac{1}{2}}$), the solution of (2.4.29) is just the negative gradient:

$$s^{(k)} = -g^{(k)}$$
 (2.4.31)

In this case we have B = -I, where I is the identity matrix. Because (2.4.31) solves (2.4.29) with respect to the two norm, the negative gradient direction $s^{(k)}$ in (2.4.31) is termed the direction of steepest descent and the algorithm using this direction at every iteration is called the steepest descent algorithm.

Unless the gradient vanishes, the steepest descent direction is clearly a descent direction, since the vectors $s^{(k)}$ and $g^{(k)}$ are bounded away from orthogonality and the directional derivative is such that

$$g^{(k)} g^{(k)} = -g^{(k)} g^{(k)} < 0$$

Consequently any of the line search techniques described in 4.2.2 above, may be combined with the steepest descent algorithm to yield a method with guaranteed global convergence.

Unfortunately, a proof of global convergence for an algorithm does not ensure that it is an efficient method. Although this method is useful for a large class of well conditioned problems, experience has shown that it can be extremely slow. Kowalik and Osborne (1968) discuss some of the reasons for this inefficiency. This weakness of the method is mainly due to the fact that the search directions generated by the algorithm are not linearly independent. However, the fact that the method only uses successive linear approximations to the objective function is another factor in its inefficiency. The steepest descent method is shown to have at best a linear rate of convergence. Proofs of global and local convergence can be found in Gill, Murray and Wright (1981). 40

4.2.4 The Method of Newton.

This is another standard method for the solution of the general minimization problem (2.4.1). The method of Newton uses successive quadratic approximations to the objective function based on the Taylor series expansion, as opposed to the linear approximation (2.4.23) used for the method of steepest descent.

The quadratic approximation to f based on the Taylor series expansion about $x^{(k)}$ is as follows:

$$f(x^{(k)} + s) \approx f(x^{(k)}) + g^{(k)}s + \frac{1}{2}s^{T}H^{(k)}s$$
 (2.4.32)

where $H^{(k)} = \nabla^2 f(x^{(k)})$ is the matrix of second partial derivatives at $x^{(k)}$ (or Hessian matrix). This quadratic approximation of f(x)is used to form an iteration sequence by forcing $x^{(k+1)}$, the next point in the sequence, to be a point where the gradient of the approximation is zero. Therefore:

$$g^{(k)} + H^{(k)} g^{(k)} = 0$$
, (2.4.33)

and hence,

$$s^{(k)} = -H^{(k)^{-1}}g^{(k)}$$
 (2.4.34)

Accordingly, this successive quadratic approximation scheme produces the method of Newton for Optimization:

$$x^{(k+1)} = x^{(k)} - H^{(k)} g^{(k)}$$
 (2.4.35)

In this case the transformation matrix B is:

$$B = -H^{(k)^{-1}}$$

and the step length $\alpha^{(k)}$ is always taken equal to 1. Note however, that the direction (2.4.34) is not necessarily a descent direction

unless the Hessian matrix is positive definite. To see this more clearly, assume the current point $x^{(k)}$ is not a stationary point (i.e. $g^{(k)} \neq 0$), and examine the projection of the Newton direction (2.4.34) onto the local gradient. By definition of a descent direction, condition (2.4.4) must hold. This leads to:

$$-g^{(k)} H^{(k)} q^{(k)} < 0 \qquad (2.4.36)$$

Clearly this condition is satisfied if $H^{(k)}$ is positive definite. If a point is encountered where $H^{(k)}$ is negative definite, the direction is an ascent direction; and when the Hessian is indefinite, there is no assurance of ascent or descent directions.

If the Hessian matrix $H^{(k)}$ is positive definite, Newton's method will minimize a quadratic function, from any starting point, in exactly one step. Therefore, we expect good convergence from the method when the quadratic model (2.4.32) is accurate. Mangasarian (1971) has shown, under mild regularity conditions on f(x), that Newton's method exhibits a quadratic rate of convergence.

4.2.5 The Modified Newton's Method.

Experience has shown that Newton's method can be unreliable for non quadratic functions. The Newton step $(\alpha^{(k)} = 1)$ will often be large when the starting point is far from the solution x^* , and there is a real possibility of divergence. It is however, possible to rectify the method in a logical and simple way to ensure a descent property to hold and to achieve a sufficient decrease in f(x) at each iteration by combining the method with a line search technique as in the method of steepest descent. That is we form the sequence of iterates:

$$x^{(k+1)} = x^{(k)} - \alpha^{(k)} H^{(k)^{-1}} g^{(k)}$$
 (2.4.37)

by choosing $\alpha^{(k)}$ either by exact line search when possible or inexact line search techniques.

This is a modified Newton's method. This method is reliable and efficient when first and second derivatives are accurate and computed inexpensively. The major difficulty in this method and in Newton's method is the need to calculate and solve the linear equation involving the Hessian matrix $H^{(k)}$ at each iteration.

Experience has also shown that the method of steepest descent tends to be effective far from the minimum but becomes less so as x^* is approached, whereas the method of Newton can be unreliable far from x^* but is very efficient as $x^{(k)}$ approaches the minimum.

4.2.6 Quasi-Newton Methods.

The theory of Quasi-Newton methods is based on the fact that an approximation to the curvature of a nonlinear function can be computed, without explicitly forming the Hessian matrix, using only first order information. These methods generate directions of search of the form:

$$s^{(k)} = -A^{(k)} \cdot g^{(k)}$$
, (2.4.38)

where $A^{(k)}$ is an n×n matrix called the metric. Methods that use directions of this form are often called "Variable Metric Methods", because $A^{(k)}$ changes at each iteration. To be precise, a variable metric method is a quasi-Newton method if it is designed so that the iterates on a quadratic function $f(x) = a + b^{T}x + \frac{1}{2}x^{T}Cx$ satisfy the condition:

$$\Delta x = C^{-1} \cdot \Delta g \quad . \tag{2.4.39}$$

Unfortunately, the literature is not precise or consistent in the use of these terms (see Avriel (1976)), therefore, we shall use these terms interchangeably. This is appropriate, since both expressions are of equal importance in the design and execution of these methods.

An iteration of a variable metric algorithm for minimizing a differentiable function f takes the following form:

Given an estimate $x^{(k)}$ of the required minimizer and a positive definite matrix $A^{(k)}$, which is an approximation to the inverse of the Hessian matrix $H^{(k)}$, apply the formula:

$$x^{(k+1)} = x^{(k)} - \alpha^{(k)} A^{(k)} g^{(k)}$$
, (2.4.40)

where $\alpha^{(k)}$ is a step length chosen by a line search procedure. Then calculate a positive definite matrix $A^{(k+1)}$, depending only on $A^{(k)}$ and the vectors:

$$\Delta x^{(k)} = x^{(k+1)} - x^{(k)}$$

$$\Delta g^{(k)} = g^{(k+1)} - g^{(k)}$$
(2.4.41)

that obeys the quasi-Newton condition:

$$\Delta x^{(k)} = A^{(k+1)} \Delta g^{(k)} . \qquad (2.4.42)$$

Various formulae to compute the successive approximations to the inverse of $H^{(k)}$, $A^{(k)}$, that satisfy the quasi-Newton condition (2.4.42), have been proposed in the literature. Two of the most

commonly used formulae are given below:

The Davidon, Fletcher and Powell : (1959) and (1963). (D.F.P)

The D.F.P. method is the first method of this type to be used. Ituses the following approximation matrix at each iteration, starting with the identity matrix I:

$$A_{(k+1)}^{(k+1)} = A_{(k)}^{(k)} + \frac{\Delta x^{(k)} \Delta x^{(k)}}{\Delta x^{(k)} \Delta g^{(k)}} - \frac{A_{(k)}^{(k)} \Delta g^{(k)} \Delta g^{(k)}}{\Delta g^{(k)} A^{(k)} \Delta g^{(k)}} . \qquad (2.4.43)$$

The Broyden, Fletcher, Goldfarb and Shanno : (1970). (B.F.G.S)

The B.F.G.S. method uses the following approximation matrix at each iteration, starting with the identity matrix I:

$$A^{(k+1)} = \left[I - \frac{\Delta x^{(k)} \cdot \Delta g^{(k)^{T}}}{\Delta x^{(k)} \Delta g^{(k)}}\right] \cdot A^{(k)} \cdot \left[I - \frac{\Delta g^{(k)} \cdot \Delta x^{(k)^{T}}}{\Delta x^{(k)} \Delta g^{(k)}}\right] + \frac{\Delta x^{(k)} \cdot \Delta x^{(k)}}{\Delta x^{(k)} \Delta g^{(k)}} + \frac{\Delta x^{(k)} \cdot \Delta x^{(k)^{T}}}{\Delta x^{(k)} \Delta g^{(k)}}\right] \cdot (2.4.44)$$

since a stationary point x^* of f is a strong local minimizer if the Hessian matrix at x^* is positive definite, it would seem desirable for the approximating matrices $\{A^{(k)}\}$ to be positive definite. Furthermore, if $A^{(k)}$ is positive definite, the local quadratic model has a unique local minimum and the search direction $s^{(k)}$ computed from (2.4.38) is a descent direction. Thus it is usual to require that the update formulae possess the property of hereditary positive definiteness, i.e. if $A^{(k)}$ is positive definite, so is $A^{(k+1)}$. The positive definiteness of the Hessian or inverse Hessian approximation can be lost through rounding errors. However, this can be eliminated by updating the Cholesky factors of the matrix, rather than an explicit representation of the elements of the matrix.

If a twice continuously differentiable function f has bounded second derivatives and the level set (2.4.7) is bounded, global convergence can be proved for a quasi-Newton method if every $A^{(k)}$ is positive definite with a bounded condition number, and if one of the line search procedures described in 4.2.2 is used to choose $\alpha^{(k)}$. The restrictions on $A^{(k)}$ ensure that the search direction remains sufficiently bounded away from orthogonality with the negative gradient. The matrices $\{A^{(k)}\}$ generated by an implementation that updates the Cholesky factors can be made to satisfy these requirements by including a procedure that explicitly bounds the condition number.

In considering whether quasi-Newton methods converge superlinearly, we note that the following property holds for a superlinearly convergent sequence $\{x^{(k)}\}_{k\in\mathbb{N}}$:

$$\lim_{k \to \infty} \frac{\|x^{(k+1)} - x^{(k)}\|}{\|x^{(k)} - x^{*}\|} = 0 \quad . \tag{2.4.45}$$

If $\alpha^{(k)} = 1$ for all k, and the sequence $\{x^{(k)}\}_{k \in \mathbb{N}}$ converges locally and linearly, convergence is superlinear if and only if the sequence $\{A^{(k)}\}$ satisfies:

$$\lim_{k \to \infty} \frac{\| (A^{(k)} - H(x^{*})) (x^{(k+1)} - x^{(k)}) \|}{\| x^{(k+1)} - x^{(k)} \|} = 0 .$$
 (2.4.46)

46

One of the most interesting properties of these updates is that it is not necessary for $A^{(k)}$ to converge to $\overline{H}(x^*)$ in order for (2.4.46) to be satisfied, and therefore the iterates with $\alpha^{(k)} = 1$ for all k can converge superlinearly even if the Hessian approximation does not converge to the true Hessian. The property (2.4.46) can be verified for both the D.F.P. and the B.F.G.S. updates under suitable assumptions. However, if step lengths other than unity are allowed, the sequence $\{\alpha^{(k)}\}_{k\in\mathbb{N}}$ must converge to unity at a sufficiently fast rate if superlinear convergence is to be verified. This is the reason for the frequent advice in the literature to initiate a step length procedure for a quasi-Newton method with a full Newton step of unity.

Most of the work on convergence of quasi-Newton methods is due to Broyden (1967) and (1970), Broyden, Dennis and Moré (1973), Powell (1971), (1975) and (1976a). The characterization (2.4.45) of superlinear convergence is due to Dennis and Moré (1974).

4.2.7 Conjugate Gradient Methods.

We have seen above that the weakness of the steepest descent method is due to the fact that the search directions generated by the method are not linearly independent and that the major difficulty in the Newton and modified Newton methods is the need to compute and solve the linear equation involving the inverse of the Hessian matrix $H^{(k)}$ at each iteration k. This suggests that a good method will have the characteristics that any t consecutive search directions (t \leq n) are linearly independent, and the curvature information (provided by the Hessian matrix) will be built up as the iterations proceed, using the observed behaviour of $f(x^{(k)})$ and $g^{(k)}$. The family of conjugate direction methods combines these two characteristics and provides the most useful general-purpose minimization methods currently available. It has been recently shown that the search directions generated by quasi-Newton methods are mutually conjugate and therefore this class of methods belong to the family of conjugate direction methods. Although quasi-Newton methods are very efficient in terms of their superlinear convergence their main drawback is the need to store an n×n matrix for the approximation of the inverse of the Hessian and the fair amount of housekeeping labour needed to compute these approximations.

In contrast to most methods for unconstrained optimization, conjugate gradient methods form a class of methods that generate directions of search without storing any matrix. They are essential in circumstances when methods based on matrix factorization are not viable because the relevant matrices are too large or too dense.

Conjugate gradient methods were originally introduced by Hestenes and Stiefel (1952) for the solution of systems of linear equations and are therefore based on the assumption that in the neighbourhood of a nondegenerate minimum point, a function behaves like a quadratic function.

The search directions generated by conjugate gradient algorithms are of the form:

$$s^{(k)} = \begin{cases} -g^{(k)} & \text{if } k = 1 \\ -g^{(k)} + \beta^{(k)} s^{(k-1)} & \text{if } k > 1 \end{cases}$$
 (2.4.47)

Various formulae in $\beta^{(k)}$ that ensure conjugacy of successive search directions have been suggested in the literature. Someof the better known of these formulae are given below:

Hestenes and Stiefel (1952):

$$\beta^{(k)} = \frac{(g^{(k+1)} - g^{(k)})^{T} g^{(k+1)}}{(g^{(k+1)} - g^{(k)})^{T} s^{(k)}} \qquad (2.4.48)$$

Fletcher and Reeves (1964):

$$\beta^{(k)} = \frac{g^{(k+1)^{T}}g^{(k+1)}}{g^{(k)^{T}}g^{(k)}} \qquad (2.4.49)$$

Polak and Ribiere (1969):

$$\beta^{(k)} = \frac{g^{(k+1)^{T}}(g^{k+1}) - g^{(k)}}{g^{(k)^{T}} g^{(k)}} . \qquad (2.4.50)$$

Dixon (1972) attributes the following formula to Myers:

$$\beta^{(k)} = -\frac{g^{(k+1)^{T}}g^{(k+1)}}{g^{(k)}g^{(k)}} \qquad (2.4.51)$$

For a wide class of functions, the conjugate gradient method with exact line search and exact arithmetic is n-step superlinearly convergent, i.e. :

$$\lim_{j \to \infty} \frac{\|x^{(nj+n)} - x^*\|}{\|x^{(nj)} - x^*\|} = 0 \quad . \tag{2.4.52}$$

However, for nonquadratic functions, the rate of convergence of the algorithm is usually only linear, unless the iterative procedure is occasionally "restarted" with a steepest descent direction. Fletcher and Reeves (1964) restart every (n+1) iterations, where n is the number of variables. In any case, the term "n-step superlinearly convergent" has little meaning when n is very large because of the large number of iterations required for the asymptotic convergence theory to hold.

A full description of the method, including historical development and recent advances of the conjugate gradient methods is given in the following section.

5. A STUDY OF CONJUGATE GRADIENT METHODS.

Conjugate gradient methods were originally proposed by Hestenes and Stiefel (1952) for the solution of systems of linear equations. Because the problem of finding the unconstrained minimizer of a quadratic function is equivalent to the problem of solving a system of linear equations, these methods have been used for this purpose also. Their application to nonquadratic functions has first been introduced by Fletcher and Reeves (1964) and is based on the fundamental assumption that in the neighbourhood of the required minimum the function is expected to behave like a quadratic function and therefore, can be approximated by one. Hence we first need to study some conjugate properties of quadratic functions.

5.1 Quadratic Functions and Conjugacy.

50

5.1.1 Basic Properties of Quadratic Functions.

Let n be a fixed integer and let f be the quadratic function:

$$f(x) = a + b^{T}x + \frac{1}{2}x^{T}Cx$$
, (2.5.1)

where C is a real symmetric $n \times n$ matrix, b is a fixed n-dimensional vector and a is a scalar.

The gradient of f at x is the vector:

$$g(x) = Cx + b$$
 . (2.5.2)

A stationary point of f is a point x such that g(x) = 0. Thus x is a stationary point of the quadratic function f if and only if x is a solution of the linear system of equations:

$$Cx = -b$$
 . (2.5.3)

The system (2.5.3) may or may not, have a solution. However, if C is non-singular there is exactly one solution, namely:

$$x^* = -C^{-1}b$$
, (2.5.4)

and x^* is the unique stationary point of f. If C is singular and x^* is a solution of (2.5.3), then every solution x of (2.5.3) is expressible in the form $x = x^* + z$, where z is a null vector of C, that is, a vector z such that Cz = 0. In other words, if x^* is a stationary point of f, then every stationary point of f differs from x^* by a null vector z of C.

Because f is quadratic we have the identity:

$$f(x+s) = f(x) + s^{T}(Cx+b) + \frac{1}{2}s^{T}Cs$$
 (2.5.5)

This follows from the fact that the quadratic approximation to f based on the Taylor series expansion (2.4.32) is exact for a quadratic function. Rewritten (2.5.5) states that:

$$f(x+s) = f(x) + s^{T} g(x) + \frac{1}{2} s^{T} H(x) s.$$
 (2.5.6)

The matrix H(x) = C is the Hessian matrix of f. If x^* is a stationary point, then, by replacing x by x^* and s by $x - x^*$ in (2.5.6) we obtain the formula:

$$f(x) = f(x^{*}) + \frac{1}{2} (x - x^{*})^{T} C(x - x^{*})$$
(2.5.7)

for f relative to a stationary point of f. Geometrically this function states that, when C is nonsingular, the stationary point $x^* = -C^{-1}b$ of f is the centre of the quadratic surface

$$f(x) = \gamma$$
, (2.5.8)

where γ is a constant.

A minimum point x^* of f is a stationary point of f and by (2.5.7) a stationary point x^* of f is a minimum point of f if and only if C is nonnegative, i.e. if and only if the inequality $s^{T}Cs \ge 0$ holds for every vector s. If $s^{T}Cs > 0$ whenever $s \ne 0$, i.e. if C is positive definite, then $x^* = -C^{-1}b$ is the unique minimum point of f. f is said to be a positive definite quadratic function if C is positive definite. The level surfaces (2.5.8) for a positive definite quadratic function f are ellipsoids having $x^* = -C^{-1}b$ as their common centre. The problem of minimizing f is therefore equivalent to the geometrical problem of finding the centre of an ellipsoid. This fact leads us to a geometrical description of the methods of conjugate directions and conjugate gradients, which is the main topic in this section.

It is important to note that the level surfaces

$$f(x) = \gamma$$
 for $\gamma > f(x^*)$

are similar ellipsoids. That is to say that if x_{α} and x_{β} are the points in which a ray emanating from the common centre x^* cuts the level surfaces $f(x) = \alpha$ and $f(x) = \beta$, respectively, then the ratio

$$\frac{\|\mathbf{x}_{\beta} - \mathbf{x}^{*}\|}{\|\mathbf{x}_{\alpha} - \mathbf{x}^{*}\|} = \mathbf{r}$$

of the distances of x_{α} and x_{β} from x^{*} is independent of the choice of this ray. This situation is illustrated in Figure 2.5.1 below:

Figure 2.5.1

To ensure the existence of the minimum point $x^* = -C^{-1}b$, we shall assume that the matrix C is positive definite.

5.1.2 Conjugacy.

Let n be a fixed integer and let C be an n×n positive definite matrix.

Two vectors x and y from \mathbb{R}^n are said to be conjugate with respect to the matrix C, if $x^TCy = 0$. Note that if C is taken to be the identity matrix I, the definition of conjugacy becomes that of orthogonality. Conjugacy is therefore a generalization of the concept of orthogonality by letting the scalar product be

$$[x,y] = x^{T} Cy$$
 (2.5.9)

Note also that if x and y are conjugate with respect to the matrix C then the vectors x and z = Cy are orthogonal.

A system of vectors $\{z^{(1)}, z^{(2)}, \dots, z^{(m)}\}$ from \mathbb{R}^n is said to be a system of conjugate vectors with respect to the matrix C, if

$$z^{(i)} c_{z}^{(j)} = 0$$
 for all $i \neq j$. (2.5.10)

Because C is a positive definite matrix, the system $\{r^{(1)}, r^{(2)}, \ldots, r^{(n)}\}$ of its eigenvectors is a system of conjugate vectors. In this case we have:

$$r^{(i)}{}^{T}Cr^{(j)} = r^{(i)}{}^{T}(\lambda_{j}r^{(j)}) = \lambda_{j}r^{(i)}{}^{T}r^{(j)} = 0$$

for $i \neq j$ (2.5.11)

where λ_i is the jth eigenvalue of C.

A system of conjugate vectors with respect to the matrix C can be constructed from any free system of vectors $x^{(1)}, \ldots, x^{(n)}$ by using the orthogonalization method of Gram-Schmidt using the scalar product (2.5.9). (See Dahlquist and Björk (1974)). This is done as follows:

Put
$$z^{(1)} = x^{(1)}$$
. Then for $i = 2, 3, ... n$ successively put
 $z^{(i)} = x^{(i)} + \sum_{j=1}^{i-1} \beta_{ij} z^{(j)}$, (2.5.12)

where the coefficients β_{ij} are chosen to make $z^{(i)} C z^{(k)} = 0$ for all k = 1,2,...,i-1. This means that β_{ij} must satisfy the equations:

$$x^{(i)} c^{T} c^{(k)} + \sum_{j=1}^{i-1} \beta_{ij} z^{(j)} c^{T} c^{(k)} = 0 . \qquad (2.5.13)$$

In principle (2.5.13) defines i-1 simultaneous equations for the i-1 unknown β_{ij} . But if we use the fact that $z^{(i)}, \ldots, z^{(i-1)}$ are mutually conjugate with respect to the matrix C, we find that they reduce to the i-1 simple equations:

$$\beta_{ij} = -x^{(i)^{T}} C z^{(j)} / z^{(j)^{T}} C z^{(j)}, \quad j = 1, \dots, i-1 \quad .$$
(2.5.14)

The denominator in (2.5.14) cannot vanish if C is positive definite, since the $x^{(j)}$ are assumed to be linearly independent (free system of vectors). Hence $z^{(j)}$ cannot vanish.

5.1.3 Conjugate Properties of Quadratic Functions.

We come now to a description of the properties of the quadratic function (2.5.1), upon which our algorithms of conjugate gradients are based.

Theorem 2.5.1:

The minimum points of the quadratic function of (2.5.1), on parallel lines, lie on an (n-1)-plane π_{n-1} through the minimum point x^{*} of f. The (n-1)-plane π_{n-1} is defined by the equation

$$s^{T}(Cx+b) = 0$$
, (2.5.15)

where s is a direction vector for these parallel lines. The vector Cs is normal to π_{n-1} .

Figure 2.5.2.

Proof:

This result is shown schematically in Figure 2.5.2 above. In this figure, the points y_1 and y_2 are, respectively, the minimum points of f on the two parallel lines L_1 and L_2 . The direction of these lines can be represented by a nonnull vector s.

At the minimum point y_1 of f on L_1 the gradient $g(y_1) = Cy_1 + b$ of f is orthogonal to L_1 and hence also to s. The point y_1 therefore satisfies equation (2.5.15). Similarly y_2 satisfies this equation. Equation (2.5.15) represents an (n-1)-plane π_{n-1} whose normal is Cs. Because $Cx^* = -b$, the minimum point x^* of f lies in π_{n-1} . Since π_{n-1} is uniquely determined by the direction vector s, it follows that the minimum points of f on all lines with direction s must lie in the (n-1)-plane π_{n-1} . Note that because Cs is orthogonal to π_{n-1} , it is orthogonal to every vector q in π_{n-1} . In other words the vector s is conjugate to every vector q in π_{n-1} with respect to the positive definite matrix C and hence the relation

$$s^{\rm T}Cq = 0$$
 (2.5.16)

holds for every vector q in π_{n-1} . Referring to Figure 2.5.2, note also that the line L_1 is given parametrically in the form $x = x_1 + \alpha s$, where x_1 is a point on L_1 and α a parameter ranging from $-\infty$ to $+\infty$.

By (2.5.5), along the line $x = x_1 + \alpha s$, we have:

$$f(x_1 + \alpha s) = f(x_1) + \alpha s^{T}(Cx_1 + b) + \frac{\alpha^2}{2} s^{T}C s.$$

And because $g(x_1) = Cx_1 + b$, this becomes:

$$f(x_1 + \alpha s) = f(x_1) + \alpha s^T g(x_1) + \frac{\alpha^2}{2} s^T C s$$
 (2.5.17)

This function of α has a minimum value when $\alpha = -s^{T}g(x_{1})/s^{T}Cs$.

Theorem 2.5.2:

Let $x^{(1)} \in \mathbb{R}^n$ and let $\{z^{(1)}, z^{(2)}, \dots, z^{(n)}\}$ be a system of conjugate vectors with respect to the positive definite matrix C of the quadratic function (2.5.1). Let Z be the affine set:

$$Z = \left\{ x = x^{(1)} + z \mid z \in [z^{(1)}, \dots, z^{(n)}] \right\}$$
(2.5.18)

where $[z^{(1)}, \ldots, z^{(n)}]$ is the subspace of the linear combinations of $z^{(1)}, z^{(2)}, \ldots, z^{(n)}$. Then:

The minimum point x^* of the quadratic function (2.5.1) over

the set Z can be calculated by minimizing f over the points $x^{(i)} \in Z$ such that

$$z^{(i)^{T}} C(x^{(i)} - x^{(1)}) = 0$$

successively. In other words:

$$f(x^{(i)} + \alpha_{i}^{*} z^{(i)}) = Min f(x^{(i)} + \alpha_{i} z^{(i)}) \Rightarrow f(x^{*}) = Min f(x)$$

$$\alpha_{i} \qquad i = 1, 2, ..., n$$
where
$$x^{*} = x^{(1)} + \alpha_{1}^{*} z^{(1)} + \alpha_{2}^{*} z^{(2)} + ... + \alpha_{n}^{*} z^{(n)}$$
The proof of this theorem is since in two lifts

The proof of this theorem is given in Appendix 1.

5.2 Conjugate Gradient Methods for Quadratic Functions.

We now proceed to develop specific computational methods for minimizing the positive definite quadratic function f of (2.5.1). These methods consist of minimizing f successively along lines. If these lines are mutually conjugate, the method is called a conjugate direction method for finding the minimum point $x^* = -C^{-1}b$ of f. By virtue of Theorem 2.5.2, a conjugate direction method terminates in m \leq n steps (if no roundoff errors occur). This fact also follows from Theorem 2.5.1, as can be seen from the following geometrical description of a conjugate direction method.

- (1) Select a point $x^{(1)}$ and a Line L_1 through $x^{(1)}$ in a direction $s^{(1)}$.
- (2) Find the minimum point $x^{(2)}$ of f on L₁.
- (3) Construct the (n-1)-plane π_{n-1} through $x^{(2)}$ which is conjugate to $s^{(1)}$.

By Theorem (2.5.1) the minimum x^* of f is in π_{n-1} . Consequently, our next search can be limited to π_{n-1} so that we have reduced the dimensionality of our space of search by one. We now repeat the process, restricting ourselves to the (n-1)-plane π_{n-1} .

- (1) Select a line L_2 in π_{n-1} through $x^{(2)}$ in a direction $s^{(2)}$.
- (2) Find the minimum point $x^{(3)}$ of f on L₂.
- (3) Construct the (n-2)-plane π_{n-2} through $x^{(3)}$ which is conjugate to $s^{(2)}$.

By Theorem (2.5.1) again with π_{n-1} playing the role of the Euclidean space E_n , the minimum point x^* of f is in π_{n-2} so that we can limit our search to π_{n-2} . Again the dimension of our space of search has been reduced by one. Proceeding in this manner we reduce the dimensionality of our space of search by one at each step.

At the nth step our space of search is the line π_1 through x^* so that the minimum point $x^{(n+1)}$ of f on π_1 coincides with the minimum point x^* . Of course, on rare occasions we have $x^{(m+1)} = x^*$ at an mth step (m < n), in which case we can terminate in m < n steps.

A conjugate gradient method is a conjugate direction method characterized by the construction in step (3) of each iteration k of the (n-k)-plane π_{n-k} , through the minimum point $x^{(k+1)}$ of f on the line L_k , which is conjugate to the direction $s^{(k)}$ of the line L_k .

5.2.1 Generation of Conjugate Gradients.

Because the function f in (2.5.1) is a positive definite quadratic function, at any point $x^{(k)}$, the gradient:

$$g^{(k)} = g(x^{(k)}) = C x^{(k)} + b$$

is available. Initially, at the chosen starting point $x^{(1)}$, only one direction is known, that of the gradient $g^{(1)}$. This is chosen as the first direction of the conjugate set, i.e.

$$s^{(1)} = -g^{(1)}$$
 (2.5.19)

The function f is then minimized along the line $L_1 = \{x \mid x = x^{(1)} + \alpha s^{(1)}\}$. The minimum point along L_1 is say $x^{(2)} = x^{(1)} + \alpha_1^* s^{(1)}$, where α_1^* is found by an exact line search. This will imply that

$$s^{(1)}{}^{T}g^{(2)} = 0$$
 . (2.5.20)

The property (2.5.20) follows from the fact that the line L_1 is tangent to the level surface $f(x) = f(x^{(2)})$ at the point $x^{(2)}$ and therefore $g^{(2)}$ is orthogonal to L_1 , hence to $s^{(1)}$.

At $x^{(2)}$, two directions are available : $g^{(2)}$ and $s^{(1)}$, and a direction $s^{(2)}$ is sought in the plane defined by these two vectors, i.e.

$$s^{(2)} = -g^{(2)} + \beta s^{(1)}$$
 (2.5.21)

for some scalar β , which will be termed the modifying constant or the update. For s⁽²⁾ to be conjugate to s⁽¹⁾ with respect to the matrix C, we require:

$$s^{(2)}^{T} C s^{(1)} = 0$$
 . (2.5.22)

The requirement (2.5.22) is equivalent to:

$$s^{(2)^{T}} C(\alpha_{1}^{*} s^{(1)}) = 0$$

and because $C(\alpha_1^* s^{(1)}) = g^{(2)} - g^{(1)}$, the conjugacy condition (2.5.22) becomes:

$$(-g^{(2)} + \beta s^{(1)})^{T}(g^{(2)} - g^{(1)}) = 0$$

and therefore

$$3 = \frac{g^{(2)}(g^{(2)} - g^{(1)})}{s^{(1)}(g^{(2)} - g^{(1)})} \qquad (2.5.23)$$

A line search is now made in the direction $s^{(2)}$ so that $g^{(3)}{}^{T}s^{(2)} = 0$, and by simple algebra this implies that:

$$g^{(3)}{}^{T}s^{(2)} = g^{(3)}{}^{T}s^{(1)}$$
 and $g^{(3)}{}^{T}g^{(2)} = g^{(3)}{}^{T}g^{(1)} = 0$.

We now continue the process by induction. Assume that at $x^{(k+1)}$, k+1 directions are available, namely $g^{(k+1)}$, $s^{(1)}$,..., $s^{(k)}$, that have the following properties:

$$s^{(1)},...,s^{(k)}$$
 are conjugate with respect to C, (2.5.24a)
 $g^{(k+1)^{T}}s^{(i)} = 0$ $i = 1,...,k$, (2.5.24b)

$$g^{(k+1)}g^{(i)} = 0$$
 $i = 1, ..., k$. (2.5.24c)

We can now use the orthogonalization process of Gram-Schmidt defined by (2.5.12), (2.5.13) and (2.5.14) above, in which the vectors x and z are replaced by - g and s respectively, to obtain:

$$s^{(k+1)} = -g^{(k+1)} + \sum_{j=1}^{k} \beta_j s^{(j)}$$
 (2.5.25)

The k conjugacy conditions to be considered here are:

$$s^{(k+1)^{T}} C s^{(i)} = 0$$
 $i = 1,...,k$,

61

but because these conditions are equivalent to:

$$\alpha_{i}^{*} s^{(k+1)} C s^{(i)} = 0$$
 $i = 1, ..., k$,

we shall use the latter for reasons that will become clearer as this analysis goes on. Equations (2.5.13) will then become:

$$g^{(k+1)}C(\alpha_{i}^{*}s^{(i)}) = \sum_{j=1}^{k} \beta_{ij} s^{(j)}C(\alpha_{i}^{*}s^{(i)}); \quad i = 1,...,k$$

And when we use the fact that $s^{(1)}, \ldots, s^{(k)}$ are conjugate (2.5.24a), we obtain

$$\beta_{ij} = \beta_{i} = \frac{g^{(k+1)} C(\alpha_{i}^{*} s^{(i)})}{s^{(i)} C(\alpha_{i}^{*} s^{(i)})} \qquad i = 1, \dots, k \quad . \quad (2.5.26)$$

We now observe that:

...

$$g^{(i+1)} - g^{(i)} = b + C(x^{(i)} + \alpha_i^* s^{(i)}) - b - C x^{(i)} = \alpha_i^* C s^{(i)}$$
.
(2.5.27)

Therefore, by substituting (2.5.27) into (2.5.26) we obtain:

$$\beta_{i} = \frac{g^{(k+1)^{T}}(g^{(i+1)}-g^{(i)})}{s^{(i)^{T}}(g^{(i+1)}-g^{(i)})} \qquad i = 1, \dots, k$$

Finally by using the orthogonality conditions (2.5.24b) and (2.5.24c) above we get:

$$\beta_i = 0$$
 for $i < k$

and hence (2.5.25) becomes
$$s^{(k+1)} = -g^{(k+1)} + \beta^{(k)} s^{(k)}$$
 (2.5.28)

where

$$\beta^{(k)} = \frac{g^{(k+1)^{T}}(g^{(k+1)} - g^{(k)})}{s^{(k)^{T}}(g^{(k+1)} - g^{(k)})}$$
(2.5.29)

which is the standard form of Hestenes and Stiefel (1952) of the conjugate gradient algorithm. Further simplifications of (2.5.29) have been suggested in the literature based on the facts that:

(1) $g^{(k+1)}{}^{T}s^{(k)} = 0$ as the line search along $s^{(k)}$ is exact, (2) $g^{(k)}{}^{T}s^{(k-1)} = 0$ as the line search along $s^{(k-1)}$ has been exact, and (3) $g^{(k+1)}{}^{T}g^{(k)} = 0$ as the function is quadratic, the search directions are conjugate and the line searches are exact.

By using (1) and (3) we obtain the formula:

$$\beta^{(k)} = -\frac{g^{(k+1)}g^{(k+1)}}{g^{(k)}g^{(k)}}$$
(2.5.30)

that Dixon (1972) attributes to Myers. If we note that

$$s^{(k)} = -g^{(k)} + \beta^{(k-1)} s^{(k-1)}$$
, (2.5.31)

the denominator of (2.5.30) becomes:

$$(-g^{(k)}+\beta^{(k-1)}s^{(k-1)})^{T}g^{(k)} = -g^{(k)}g^{(k)}+\beta^{(k-1)}s^{(k-1)}g^{(k)},$$

and by using (2) we obtain the formula:

$$\beta^{(k)} = \frac{g^{(k+1)}g^{(k+1)}}{g^{(k)}g^{(k)}}$$
(2.5.32)

of Fletcher and Reeves (1964). If we now consider (2.5.29) again and use (1), (2) and (2.5.31) we obtain the formula:

$$\beta^{(k)} = \frac{g^{(k+1)} (g^{(k+1)} - g^{(k)})}{g^{(k)} g^{(k)}}$$
(2.5.33)

of Polak and Ribiere (1969).

These formulae for the update $\beta^{(k)}$, generate the same set of conjugate directions on quadratic functions. However, when, as is often the case, these formulae are applied on non-quadratic functions, different directions result as * is no longer correct.

One of the major advantages in conjugate gradient methods comes from the observation (2.5.27); because the matrix C of second derivatives of f is constant, one can find out curvature information by observing the way the first derivatives change and therefore avoid the storage of matrices and any computation involving matrices.

5.2.2 Convergence Properties.

We shall now discuss the convergence properties of conjugate gradient methods when the objective function is a positive definite quadratic function.

It is well known that when applied on a positive definite quadratic function, the conjugate gradient method using any of the formulae above to compute the update $\beta^{(k)}$ will terminate in

at most n steps from any starting point $x^{(1)}$, provided the starting direction is the steepest descent direction $s^{(1)} = -g^{(1)}$. This result follows from Theorem 2.5.2 above. It can also be shown that the number of steps required for termination to occur, is equal to the number of distinct eigenvalues of the matrix C. For a proof of this result see, for example, Hestenes (1980).

Crowder and Wolfe (1971) have shown that if the wrong starting direction is used, then the rate of convergence is at best linear. This result has been extended by Powell (1976), to show that if the objective function is a positive definite quadratic function and if the initial search direction is an arbitrary descent direction, then if termination does not occur within n+1 steps, the rate of convergence is only linear. Thus superlinear convergence never occurs even when f is quadratic. Furthermore, Powell (1976) also found that it can happen that linear convergence is obtained and every sequence of (1+1) consecutive search directions is mutually conjugate, where l is a positive integer less than (n-1). However, he also found conditions to improve on $x^{(1)}$ and $s^{(1)}$ that are necessary and sufficient for termination to occur in a finite number of steps. This result of Powell's also shows that if s⁽¹⁾ is fixed and if the components of $x^{(1)}$ are chosen at random, for instance from the uniform distribution in [-1, 1], then the probability of obtaining termination by chance, when $n \ge 3$ and there are no degeneracies, is zero. Thus a linear rate of convergence is usual when the conjugate gradient algorithm is applied on a general convex quadratic function and when both $s^{(1)}$ and $x^{(1)}$ are arbitrary.

5.3 Conjugate Gradient Methods for General Functions.

The conjugate gradient algorithm for minimizing a quadratic function can be combined with Newton's method for minimizing a non-quadratic function f to obtain an effective method for finding the minimum x^* of f. We assume here of course that the Hessian matrix of f is positive definite. The only significant modification to the method is that the step lengths $\alpha^{(k)}$ are no longer easily provided by an exact line search but they are usually computed by an inexact line search procedure. The finite termination property of the method on quadratic functions suggests that the definition (2.5.28) should be abandoned after a cycle of linear searches, and that $s^{(k)}$ should then be set to the steepest descent direction $-g^{(k)}$. This strategy is known as restarting; it is also known as "resetting" or "reinitialization". The combined method proceeds as follows:

(1) Select a starting point $x^{(1)}$.

(2) Construct the Newton approximation:

$$F(s) = f(x^{(1)}+s) = f(x^{(1)}) + g^{(1)}s + \frac{1}{2}s^{T}H(x^{(1)})s$$

- (3) With $s^{(1)} = 0$ as the initial point of F, use a conjugate gradient routine to obtain the minimum point $s^{(n+1)}$ of F.
- (4) Repeat computations (2) and (3) with $x^{(1)}$ replaced by $x^{(1)} + s^{(n+1)}$. Terminate if $|g^{(k)}|$ is so small that $x^{(k)} = x^{(1)} + s^{(k(n+1))}$ is an acceptable estimate of the minimum point x^* of f.

The approximation however, is not done explicitly, and since it

is hardly possible to obtain an exact step length without major complications, inexact line search procedures are used instead.

5.3.1 Conjugate Gradients Without Exact Line Searches.

When the criterion (2.4.20) of exact line search is relaxed then the equation following (2.5.27) does not give:

$$\beta_i = 0$$
, for $i < k$,

and the correct calculation of β_i would involve the storage of all $g^{(i)}$. Dixon (1975) gives a modification of the strategy for generating conjugate gradients, that makes the accurate line search (2.4.20) unnecessary. His modification is based on estimating the differences

$$z^{(k)} = x^{(k)} - x^{(k)}$$
 and $w^{(k)} = g^{(k)} - g^{(k)}$

using the properties of quadratic functions, where $x^{(k)}$ and $g^{(k)}$ denote the variables and gradients calculated with an inexact line search, and $x^{(k)}^*$ and $g^{(k)}^*$ denote the variables and gradients that would have been calculated if the line searches were exact. In particular the vector $w^{(k)}$ is used to ensure that the direction $(x^{(k+1)}-x^{(k)})$ is parallel to $(x^{(k+1)}-x^{(k)})$. Further details of the method can be found in Dixon (1975).

5.3.2 Restarting Procedures.

It is usually suggested that, when using a conjugate gradient method to minimize non-quadratic functions, the procedure should be restarted at regular intervals (say after n steps for an n-dimensional problem) with a steepest descent step. An apparent advantage of this strategy is that if the iterates progress from a non-quadratic region into a neighbourhood of the solution in which f(x) is closely approximated by a quadratic, accumulated errors from previous iterations will not interfere with the expected good behaviour of the algorithm.

Fletcher (1980) reckons that for some large problems with certain types of symmetry it might be appropriate to restart more frequently than on every n iterations. His analysis suggests that on large problems for which the conjugate gradient methods are suitable, restarting with the steepest descent direction every n iterations is an irrelevant consideration. What might be preferable is to restart every m << n iterations where m is somehow determined by the symmetry. Unfortunately it is not obvious how to choose an m in the algorithm.

Restarting with the steepest descent direction is also based on the questionable assumption that the reduction in f(x) along the restart direction will be greater than that obtained if the usual formula were used. However, Powell (1977) shows by example that this is not always true, and in fact the reduction at the restart iteration is often poor compared with the reduction that would have occurred without restarting. Although it would seem useful if a cycle of n iterations could commence with the last direction of the previous cycle, this idea must be applied with some care.

If, when applied to a quadratic function a conjugate gradient algorithm takes an arbitrary initial search direction $s^{(1)}$, the

required conjugacy relations may not hold because $g^{(1)}$ is no longer a linear combination of the search directions. However, one can use the strategy of Beale (1972) to derive conjugate directions without having to start with the steepest descent direction. Therefore to ensure that the successive directions are conjugate, the following recurrence relation must be used:

$$s^{(k)} = -g^{(k)} + \beta^{(k-1)} s^{(k-1)} + \gamma^{(k)} s^{(1)}$$
(2.5.34)

where $\beta^{(k-1)}$ is given by (2.5.29) and where $\gamma^{(k)}$ is:

$$\gamma^{(k)} = \frac{g^{(k)} g^{(2)} - g^{(1)}}{s^{(1)} g^{(2)} - g^{(1)}}$$

This strategy of Beale (1972) has been tried by McGuire and Wolfe (1973) who found their numerical results rather disappointing. Powell (1977) however, has turned their difficulties to an advantage because a restart is needed when these difficulties occur, and obtains an efficient restarting procedure that takes account of the objective function automatically and that does not abandon the second derivative information that is found by the previous searches. Powell's restart is based on the fact that (2.5.34) can be extended to non-quadratic problems by computing a cycle of n directions: for k = 1, 2, ..., n.

$$s^{(k)} = -g^{(k)} + \beta^{(k-1)} s^{(k-1)} + \gamma^{(k)} s^{(i)}, \qquad (2.5.35)$$

where

$$\gamma^{(k)} = \frac{g^{(k)}(g^{(i+1)} - g^{(i)})}{s^{(i)}(g^{(i+1)} - g^{(i)})}$$
(2.5.36)

The direction s⁽ⁱ⁾ is known as the restart direction and is the last direction of the previous cycle along which a linear search was made.

When minimizing a non quadratic function, $s^{(k)}$ as defined in (2.5.35) may not be a descent direction, even if exact line searches are made; this implies that the method may generate a poor direction of descent. Steps must therefore be taken to replace this direction, if necessary, by the usual conjugate gradient direction. A typical requirement for a search direction to be suitable is that $s^{(k)}$ should be "sufficiently downhill"; for example, we may impose a condition such as:

$$-g^{(k)} s^{(k)} \ge \rho \| s^{(k)} \| . \| g^{(k)} \| , \qquad (2.5.37)$$

for some positive value ρ and where $\|\cdot\|$ denotes the Euclidean norm. If this requirement is not satisfied, a new cycle commences with s^(k-1) as the restart direction and with s^(k) computed from (2.4.35).

If an inexact line search is used, condition (2.5.37) should be checked at trial step lengths with the restart direction. This will ensure that, if the direction computed from the three term formula (2.5.35) is not to be used, the restart direction will be a descent direction.

Chapter 3

Efficiency and Convergence Properties

of Conjugate Gradient Methods

1. INTRODUCTION AND PRELIMINARIES.

4

Conjugate gradient methods form a class of methods that generate directions of search without storing any matrix. They aim to solve the unconstrained minimization problem:

Minimize
$$f(x)$$
, $x \in \mathbb{R}^n$ (3.1.1)

by a sequence of line searches:

$$x^{(k+1)} = x^{(k)} + \alpha^{(k)} s^{(k)}$$
, (3.1.2)

starting from a user supplied estimate $x^{(1)}$ of the minimizer x^* . If the line search is exact, the stepsize $\alpha^{(k)}$ taken by the algorithm in the direction $s^{(k)}$, is defined by:

$$\alpha^{(k)} = \operatorname{Arg Min}_{\alpha} f(x^{(k)} + \alpha s^{(k)}) .$$
 (3.1.3)

In practice however, an exact line search is not usually possible and one accepts any value of $\alpha^{(k)}$ that satisfies certain standard conditions. Fletcher (1980) suggests that $\alpha^{(k)}$ is such that $x^{(k+1)}$ satisfies the condition:

$$|g^{(k+1)^{T}}s^{(k)}| \leq -\sigma g^{(k)^{T}}s^{(k)},$$
 (3.1.4)

together with the Goldstein (1965) requirement:

$$f(x^{k+1}) \leq f(x^{(k)}) + \rho \alpha^{(k)} g^{(k)^{T}} s^{(k)}$$
, (3.1.5)

where $g^{(k)} = \nabla f(x^{(k)})$ is the gradient vector at $x^{(k)}$, and where $\rho \in (0, \frac{1}{2}), \sigma \in (0, 1)$ and $\rho < \sigma$.

The search direction s^(k) is usually defined so that:

$$g^{(k)}{}^{T}s^{(k)} < 0$$
 (3.1.6)

holds for all k such that $g^{(k)} \neq 0$, which ensures that f(x) can be decreased in the line search. Hence condition (3.1.4) ensures that the modulus of the slope is reduced by a factor σ or less in the line search (see Fletcher (1980)). Specifically, the search direction $s^{(k)}$, for conjugate gradient methods is defined as follows:

$$s^{(1)} = -g^{(1)}$$

$$s^{(k+1)} = -g^{(k+1)} + \beta^{(k)} s^{(k)}, k > 1$$
(3.1.7)

Various formulae for $\beta^{(k)}$ have been suggested in the literature, but for the purpose of this thesis, attention will be focussed on the Fletcher-Reeves and the Polak-Ribière versions of conjugate gradient algorithms, for which $\beta^{(k)}$ is defined respectively as follows:

- The Fletcher-Reeves Update (1964):

$$\beta^{(k)} = \|g^{(k+1)}\|^2 / \|g^{(k)}\|^2 . \qquad (3.1.8)$$

- The Polak-Ribière Update (1969):

$$\beta^{(k)} = g^{(k+1)^{T}} (g^{(k+1)} - g^{(k)}) / ||g^{(k)}||^{2} \qquad (3.1.9)$$

where $| \cdot |$ denotes the Euclidean norm.

In what follows we shall assume that the level set:

{x :
$$f(x) \leq f(x^{(1)})$$
} (3.1.10)

is bounded. This assumption will ensure that $\alpha^{(k)}$ is well defined for all k.

2. DESCENT PROPERTY AND GLOBAL CONVERGENCE OF THE FLETCHER-REEVES METHOD.

2.1 The Case of Exact Line Search.

2.1.1 Descent Property.

It is clear that $s^{(1)}^{T} \cdot g^{(1)} = -g^{(1)}^{T} \cdot g^{(1)} < 0$, so the descent property (3.1.6) holds on the first iteration for any conjugate gradient algorithm. Moreover, the line search being exact we have:

$$g^{(k+1)^{T}}s^{(k)} = 0$$
 for $k \ge 1$ (3.2.1)

and therefore from (3.1.7) and (3.2.1) it follows that:

$$g^{(k+1)^{T}} s^{(k+1)} = g^{(k+1)^{T}} (-g^{(k+1)} + \beta^{(k)} s^{(k)})$$
$$= - \|g^{(k+1)}\|^{2} < 0 \quad . \tag{3.2.2}$$

This shows that a descent property holds on all iterations for any conjugate gradient formula and in particular for that of Fletcher-Reeves.

2.1.2 Global Convergence.

Powell (1983) shows that if the level set (3.1.10) is bounded, if $\alpha^{(k)}$ is defined so that (3.2.1) holds for all k, and if f(x) is twice continuously differentiable, then the Fletcher-Reeves method achieves the limit:

$$\lim_{k \to \infty} \inf \|g^{(k)}\| = 0 . \tag{3.2.3}$$

His method of proof is of interest to what will follow in the next two chapters and is therefore given below.

From the definition of s^(k) and exact line search, we deduce

the equation:

$$s^{(k)} \|^{2} = \|g^{(k)}\|^{2} + \beta^{(k-1)}\|^{2} s^{(k-1)}\|^{2}$$
$$= \|g^{(k)}\|^{2} + \beta^{(k-1)}\|^{2} \left[\|g^{(k-1)}\|^{2} + \beta^{(k-2)}\|^{2}\|s^{(k-2)}\|^{2}\right]$$
$$= -----$$
$$= \sum_{k=1}^{k} \left\{\sum_{j=k}^{k-1} \beta^{(j)}\right\} \|g^{(k)}\|^{2} = \sum_{k=1}^{k} \frac{\|g^{(k)}\|^{4}}{\|g^{(k)}\|^{2}}, \quad (3.2.4)$$

where the product is defined to be one if $\ell = k$, and where the last line depends on the value (3.1.8). Further, we recall that $\|g^{(k)}\|$ is bounded above because $x^{(k)}$ is in the level set (3.1.10). Therefore if (3.2.3) is not true, then there exists a constant ε , say, such that

$$\|g^{(k)}\| \ge \varepsilon > 0$$
 for all k (3.2.5)

and hence (3.2.4) gives:

 $\|s^{(k)}\|^2 \leq ck$

where c is a positive constant. From the definition of $\alpha^{(k-1)}$ and $s^{(k)}$, it follows that:

$$\cos \theta^{(k)} = -s^{(k)^{T}} g^{(k)} / (\|s^{(k)}\| \cdot \|g^{(k)}\|)$$
(3.2.6)

can be written

$$\cos \theta^{(k)} = \|g^{(k)}\| / \|s^{(k)}\|,$$

and because $\|g^{(k)}\|$ is also bounded above in the level set (3.1.10), we have:

$$\cos^2 \theta^{(k)} \ge c_1/k$$

which clearly implies that the series $\sum_k \cos^2 \theta^{(k)}$ is divergent. On the other hand, by letting Ω be an upper bound on the induced matrix norms $\|\nabla^2 f(x)\|$, for x in the level set (3.1.10), we obtain by a simple Taylor expansion about $x^{(k)}$ that:

$$f(x) \leq f(x^{(k)}) + (x-x^{(k)})^T g^{(k)} + \frac{1}{2} \Omega \|x-x^{(k)}\|^2$$
 (3.2.7)

for any x in the level set (3.1.10). Because $x^{(k+1)}$ is in (3.1.10), relation (3.2.7) holds when x is replaced by $x^{(k+1)}$. Therefore we obtain:

$$f(x^{(k+1)}) \leq f(x^{(k)}) + (x^{(k+1)} - x^{(k)})^T g^{(k)} + \frac{1}{2} \Omega \|x^{(k+1)} - x^{(k)}\|^2$$

From (3.1.2) we have $x^{(k+1)} - x^{(k)} = \alpha^{(k)} s^{(k)}$ where $\alpha^{(k)}$ is such that (3.1.3) is satisfied. It then follows that:

$$f(x^{(k+1)}) \leq Min_{\alpha} \left[f(x^{(k)}) + \alpha s^{(k)} \frac{T}{k} + \frac{1}{2} \Omega \alpha^2 \|s^{(k)}\|^2 \right].$$
 (3.2.8)

The minimum value of the right hand side of (3.2.8) with respect to α , is obtained by computing the derivative with respect to α of the expression between squared brackets and making it equal to zero, i.e.

 $s^{(k)^{T}}g^{(k)} + \Omega \alpha \|s^{(k)}\|^{2} = 0$.

It therefore follows that the minimum value is obtained when

$$\alpha^{(k)} = -\frac{s^{(k)} g^{(k)}}{\Omega \|s^{(k)}\|^2} \qquad (3.2.9)$$

By substituting (3.2.9) into (3.2.8) and by using (3.2.6) we obtain:

$$f(x^{(k+1)}) \leq f(x^{(k)}) + \left[-\frac{s^{(k)} g^{(k)}}{\Omega \|s^{(k)}\|^2} s^{(k)} g^{(k)} + \frac{1}{2} \frac{\Omega}{\Omega^2} \left(\frac{s^{(k)} g^{(k)}}{\|s^{(k)}\|^2} \right) s^{(k)} \|^2 \right]$$

$$= f(x^{(k)}) - \frac{1}{2\Omega} \left[\frac{s^{(k)} g^{(k)}}{\|s^{(k)}\| \cdot \|g^{(k)}\|} \right]^2 \cdot \|g^{(k)}\|^2$$

$$= f(x^{(k)}) - \frac{1}{2\Omega} \cos^2 \theta^{(k)} \cdot \|g^{(k)}\|^2$$

Thus, because f(x) is bounded below in the level set (3.1.10), the series $\sum_{k} \cos^{2} \theta^{(k)} \|g^{(k)}\|^{2}$ is convergent; and because of (3.2.5), this contradicts the fact that $\sum_{k} \cos^{2} \theta^{(k)}$ is divergent established above. It therefore follows that (3.2.5) is false and the limit (3.2.3) must be achieved.

2.2 The Case of Inexact Line Search.

Al-Baali (1985) extends Powell's result to show that even for an inexact line search, the descent property (3.1.6) holds for all k and global convergence is achieved for the Fletcher-Reeves method. Again his methods of proof are of importance to what will follow in the next two chapters and are therefore given below.

2.2.1 Descent Property.

Theorem 3.2.1: (Al-Baali (1985)).

If an $\alpha^{(k)}$ is calculated which satisfies (3.1.4) with $\sigma \in (0, \frac{1}{2}]$ for all k such that $g^{(k)} \neq 0$, then the descent property for the Fletcher-Reeves method holds for all such k.

Proof:

The method of proof is to show by induction that the inequalities:

$$-\sum_{j=0}^{k-1} \sigma^{j} \leq \frac{g^{(k)} s^{(k)}}{\|g^{(k)}\|^{2}} \leq -2 + \sum_{j=0}^{k-1} \sigma^{j}$$
(3.2.10)

hold for all k such that $g^{(k)} \neq 0$. It will then follow inductively that the descent property holds. For k = 1, (3.2.10) is clearly satisfied. Now assume that it is true for any $k \ge 1$. Since

$$\sum_{j=0}^{k-1} \sigma^{j} < \sum_{j=0}^{\infty} \sigma^{j} = \frac{1}{1-\sigma} , \qquad (3.2.11)$$

it is clear that the right hand side of (3.2.10) is negative for any σ in $(0, \frac{1}{2}]$ and hence the descent property (3.1.6) holds on iteration k. From the definition of $s^{(k+1)}$, (3.1.7) and that of $\beta^{(k)}$ (3.1.8) it follows that

$$\frac{g^{(k+1)^{T}}s^{(k+1)}}{\|g^{(k+1)}\|^{2}} = -1 + \frac{g^{(k+1)^{T}}s^{(k)}}{\|g^{(k)}\|^{2}}$$

and therefore by using (3.1.4) and (3.1.6) we obtain:

$$-1 + \sigma \frac{g^{(k)} s^{(k)}}{\|g^{(k)}\|^{2}} \leq \frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 - \sigma \frac{g^{(k)} s^{(k)}}{\|g^{(k)}\|^{2}}$$

We now use the induction assumption (3.2.10) to obtain:

$$-1 - \sigma \sum_{j=0}^{k-1} \sigma^{j} \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 + \sigma \sum_{j=0}^{k-1} \sigma^{j} . \quad (3.2.12)$$

On the other hand we have:

$$\sigma \sum_{j=0}^{k-1} \sigma^{j} = \frac{\sigma - \sigma^{k+1}}{1 - \sigma}$$
$$= \frac{-1 + \sigma}{1 - \sigma} + \frac{1 - \sigma^{k+1}}{1 - \sigma}$$
$$= -1 + \sum_{j=0}^{k} \sigma^{j} \qquad (3.2.13)$$

Finally, by substituting (3.2.13) into (3.2.12) we obtain:

$$-\sum_{j=0}^{k} \sigma^{j} \leq \frac{g^{(k+1)} \sum_{s=0}^{T} (k+1)}{\|g^{(k+1)}\|^{2}} \leq -2 + \sum_{j=0}^{k} \sigma^{j}$$

which is (3.2.10) with k replaced by k+1. Thus the induction is complete.

2.2.2 Global Convergence.

As a consequence of the descent property that has just been shown above, Al-Baali (1985) also proves a theorem for the global convergence of the Fletcher-Reeves method with an inexact line search satisfying (3.1.4) and (3.1.5).

Theorem 3.2.2: (Al-Baali (1985)).

If the level set (3.1.10) is bounded, if f(x) is twice continuously differentiable, and if an inexact line search satisfying (3.1.4) and (3.1.5) with $\rho < \sigma < \frac{1}{2}$ is used, then the Fletcher-Reeves method achieves the limit (3.2.3).

Proof:

From the definition of $s^{(k)}$ in (3.1.7) we have:

$$\| s^{(k)} \|^{2} = \| g^{(k)} \|^{2} - 2\beta^{(k-1)} g^{(k)^{T}} s^{(k-1)} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2}$$
(3.2.14)

On the other hand from (3.1.4), (3.2.10) and (3.2.11) it follows that:

$$|g^{(k)^{T}} s^{(k-1)}| \leq -\sigma g^{(k-1)^{T}} s^{(k-1)} \leq \frac{\sigma}{1-\sigma} \|g^{(k-1)}\|^{2}$$

which can be substituted into (3.2.14) to give:

$$\| \mathbf{s}^{(\mathbf{k})} \|^{2} \leq \| \mathbf{g}^{(\mathbf{k})} \|^{2} + \frac{2\sigma}{1-\sigma} \beta^{(\mathbf{k}-1)} \| \mathbf{g}^{(\mathbf{k}-1)} \|^{2} + \beta^{(\mathbf{k}-1)^{2}} \| \mathbf{s}^{(\mathbf{k}-1)} \|^{2}$$

and by using the special form of the Fletcher-Reeves beta in (3.1.8) and a similar induction argument as that of (3.2.4) in Powell's proof, we obtain:

$$\| \mathbf{s}^{(\mathbf{k})} \|^{2} \leq \left(\frac{1+\sigma}{1-\sigma} \right) \| \mathbf{g}^{(\mathbf{k})} \|^{4} \sum_{\ell=1}^{\mathbf{k}} \| \mathbf{g}^{(\ell)} \|^{-2} .$$
(3.2.15)

Further we recall again that $\|g^{(k)}\|$ is bounded above in the level set (3.1.10); therefore if (3.2.3) is not true, then there exists a constant ε , say, such that (3.2.5) is true. Hence (3.2.15) gives:

$$\|s^{(k)}\| \leq c_1^k$$
, (3.2.16)

where c_1 is a positive constant. From (3.2.10) and (3.2.11) it follows that:

$$\cos \theta^{(k)} \ge \left(\frac{1-2\sigma}{1-\sigma}\right) \frac{\|g^{(k)}\|}{\|s^{(k)}\|}, \qquad (3.2.17)$$

where $\cos \theta^{(k)}$ is as defined in (3.2.6). Because $\sigma < \frac{1}{2}$ we obtain from (3.2.16) and (3.2.17) that

$$\sum_{k} \cos^{2} \theta^{(k)} \ge \left(\frac{1-2\sigma}{1-\sigma}\right)^{2} \sum_{k} \|g^{(k)}\|^{2} / \|s^{(k)}\|^{2}$$
$$\ge c_{2} \sum_{k} 1/k$$
(3.2.18)

where c_2 is a positive constant. Hence the series $\sum_k \cos^2 \theta^{(k)}$ diverges. However, it is possible to contradict this result using the line search conditions. If Ω is an upper bound on $\|\nabla^2 f(x)\|$, where x is any point in the level set (3.1.10), we have

$$g^{(k+1)}{}^{T}s^{(k)} \leq g^{(k)}{}^{T}s^{(k)} + \Omega\alpha^{(k)} ||s^{(k)}||^{2}$$

Then by using (3.1.4) we obtain:

$$\alpha^{(k)} \geq -\frac{1-\sigma}{\Omega \|s^{(k)}\|^2} g^{(k)} s^{(k)}$$

which can be substituted into (3.1.5), and by using (3.1.6) and (3.2.6) it follows that:

$$f(x^{k+1}) \leq f(x^{(k)}) - c_3 \|g^{(k)}\|^2 \cos^2 \theta^{(k)},$$

where $c_3 = \rho(1-\sigma)/\Omega > 0$. Thus, since f(x) is bounded, $\sum_k \cos^2 \theta^{(k)} \| g^{(k)} \|^2$ is convergent. Because $\| g^{(k)} \|$ is bounded below this contradicts (3.2.18). Since this contradiction arises from (3.2.5) it follows that (3.2.5) is false and hence (3.2.3) is true.

3. THE POLAK-RIBIÈRE METHOD.

3.1 Comparison with the Fletcher-Reeves Method.

3.1.1 Computational Comparison.

In numerical computations, it is usually found that the method of Polak-Ribière is generally far more successful than that of Fletcher-Reeves.

Powell (1977) mentions a particular minimization problem of 165 variables that gives the energy of a model of an atomic system and the least value gives the structure of the nuclei when a gas condenses. This problem was first solved using the Fletcher-Reeves algorithm which showed some slow progress for several iterations and the required minimum was only obtained by forcing the algorithm to restart more often than every n iterations. Then using the same starting point, the Polak-Ribière method only took twelve iterations to find the required minimum to six decimals accuracy without any restarts.

In this thesis too, the two methods are tested and compared. We used seven different test problems each of which considered with 26 different numbers of variables, resulting in a total of 182 cases. These test problems are described in Chapter 7. The results obtained by the two methods on each individual case are given in Appendix 2, Tables (2.1.i) and (2.2.i) i = 1,2,...,7 whereas the overall results with the comparison of the figures for the two methods are given in Appendix 3. Tables (3.1) and (3.2). These results confirm the conjecture that the Polak-Ribière method is numerically far more efficient than that of Fletcher-Reeves. Out of the 182 cases considered, only on nine occasions was the Fletcher-Reeves method slightly better than that of Polak-Ribière; in all the other cases, the Polak-Ribière method proved to be far more efficient. The overall comparison results shown in Appendix 3, Table (3.2), show that the Polak-Ribière algorithm obtains the required minima of all the 182 cases in 47%, 44% and 45% less than the Fletcher-Reeves algorithm, in terms of number of iterations (NI), number of function evaluations (NF) and index of computational labour (NC) respectively, the index of computational labour being defined as NC = NF + n.NG, where n is the number of variables and NG the number of gradient evaluations.

3.1.2 Theoretical Explanations.

Powell (1977) also gives a remark that explains the theoretical reasons for this inefficiency of the Fletcher-Reeves method and how this

inefficiency is automatically avoided when the Polak-Ribière method is used instead. His argument is based on Figure 3.3.1 below:

Figure 3.3.1

The definition of $\theta^{(k)}$.

that gives the equation:

$$\|s^{(k)}\| = \sec \theta^{(k)} \cdot \|g^{(k)}\|$$
 (3.3.1)

Then, the identity:

$$\beta^{(k)} \| s^{(k)} \| = \tan \theta^{(k+1)} \cdot \| g^{(k+1)} \|$$
(3.3.2)

follows if k is replaced by k+1 in the Figure. By eliminating $\| s^{(k)} \|$ from (3.3.1) and (3.3.2) and substituting the formula (3.1.8) for $\beta^{(k)}$ of Fletcher-Reeves we obtain:

$$\tan \theta^{(k+1)} = \sec \theta^{(k)} \cdot \|g^{(k+1)}\| / \|g^{(k)}\|$$

>
$$\tan \theta^{(k)} \|g^{(k+1)}\| / \|g^{(k)}\| . \qquad (3.3.3)$$

Powell (1977) then notes that if $\theta^{(k)}$ is close to $\pi/2$, the iteration may take a very small step, and $(g^{(k+1)} - g^{(k)})$ is therefore small too. Thus the ratio $||g^{(k+1)}|| / ||g^{(k)}||$ is close to 1. It follows from (3.3.3) that $\theta^{(k+1)}$ is also close to $\pi/2$ leading to a slow progress again on the next iteration. Suppose

that the early iterations of the algorithm have made $\theta^{(k)} > 0$, but a region in the space of the variables has been reached where the objective function is the quadratic function:

$$f(x) = \frac{2}{x_1} + x_2^2$$
 (3.3.4)

In this case the line search along $s^{(k)}$ makes $||g^{(k+1)}|| / ||g^{(k)}||$ equal to sin $\theta^{(k)}$. Therefore from the first line of (3.3.3), we obtain $\theta^{(k+1)}$ equals $\theta^{(k)}$. Thus the angle between the search direction and the negative gradient remains constant for all iterations, which is highly inefficient if $\theta^{(k)}$ is close to $\pi/2$. This kind of inefficiency however, is corrected by a steepest descent direction. Alternatively, if the Polak-Ribière formula for $\beta^{(k)}$, (3.1.9) is used instead, Powell uses the equations (3.3.1) and (3.3.2) to show that the behaviour just described does not occur. The definition of $\beta^{(k)}$ (3.1.9) provides the bound:

$$\beta^{(k)} \leq \|g^{(k+1)}\| \cdot \|g^{(k+1)} - g^{(k)}\| / \|g^{(k)}\|^2 . \qquad (3.3.5)$$

So, the elimination of $\|s^{(k)}\|$ from (3.3.1) and (3.3.2) gives the inequality

$$\tan \theta^{(k+1)} \leq \sec \theta^{(k)} \cdot \|g^{(k+1)} - g^{(k)}\| / \|g^{(k)}\| . \quad (3.3.6)$$

It then follows that if $\theta^{(k)}$ is close to $\pi/2$ and if this causes the step from $x^{(k)}$ to $x^{(k+1)}$ to be so small that the change $(g^{(k+1)} - g^{(k)})$ is much less than $||g^{(k)}||$, then tan $\theta^{(k+1)}$ is much less than sec $\theta^{(k)}$. Therefore, the search direction $s^{(k+1)}$ is automatically turned towards the steepest descent direction.

In this thesis too, we consider a similar quadratic function

to that of (3.3.4) to investigate the effect of the use of an inexact line search on the loss of conjugacy of the two methods. We consider the quadratic function:

$$f(x) = a x_1^2 + x_2^2$$
, $a \ge 1$. (3.3.7)

We exclude the cases a < 0 and $0 \le a < 1$ to avoid infinite solutions when a < 0 and to be able to make a as large as possible in order to make the objective function as ill-conditioned as possible due to the difference between the magnitudes of the eigenvalues of the Hessian matrix of f.

Starting from an initial estimate $x^{(1)} = (x_1^{(1)}, x_2^{(1)})$, of the minimizer $x^* = (0, 0)^T$ we obtain:

$$f(x^{(1)}) = a x_1^{(1)^2} + x_2^{(1)^2}$$

$$g^{(1)} = 2(a x_1^{(1)}, x_2^{(1)})^T \text{ and } H = 2 \begin{bmatrix} a & 0 \\ 0 & 1 \end{bmatrix}$$

$$s^{(1)} = -g^{(1)} = -2(a x_1^{(1)}, x_2^{(1)})^T$$

We shall now consider the cases of exact and inexact line searches separately.

a) Exact Line Search:

Since f is a two-dimensional quadratic function, an exact line search will achieve the required minimum in 2 steps if $a \neq 1$ and in one step if a = 1. In any case if we let:

$$K_{i} = a^{i} x_{i}^{(1)^{2}} + x_{2}^{(1)^{2}}, \text{ for } i = 1, 2, ...,$$

$$K = K_{2}^{2} / K_{3} \text{ and}$$

$$A = K_{4} K_{2} / K_{3}^{2},$$

we obtain:

a1. First Iteration:

 $\Phi(\alpha) = f(x^{(1)} + \alpha s^{(1)}) = 4K_3 \alpha^2 - 4K_2 \alpha + K_1$

$$\alpha^{*} = \frac{K_{2}^{2}K_{3}}{x^{(2)}} = \frac{(a-1)x_{1}^{(1)} x_{2}^{(1)}}{K_{3}} \begin{bmatrix} -x_{2}^{(1)} \\ a^{2} x_{1}^{(1)} \end{bmatrix}$$

$$f(x^{(2)}) = \Phi(\alpha^*) = K_1 - K$$
.

Note that $K_1 = f(x^{(1)})$ and that if a = 1 then $\alpha^* = \frac{1}{2}$, $x^{(2)} = (0, 0)^T$, $K_1 = f(x^{(1)})$ and $f(x^{(2)}) = 0$. If a > 1 then $0 < \alpha^* < \frac{1}{2}$ and $0 < K < f(x^{(1)})$. K then represents the reduction in the function value. We now suppose that a > 1 and proceed with the next iteration.

a2. Second Iteration:

$$g^{(2)} = \frac{2(a-1)a x_1^{(1)} x_2^{(1)}}{K_3} \begin{bmatrix} -x_2^{(1)} \\ a x_1^{(1)} \end{bmatrix}$$
$$\beta^{(1)} = \beta^{(1)} (F.R) = \beta^{(1)} (P.R) = \frac{a^2 x_1^{(1)^2} x_2^{(1)^2} (a-1)^2}{K_3^2}$$

Note that $\lim_{a\to\infty} \beta^{(1)} = \lim_{a\to\infty} \frac{c_{onl}t}{2} = 0$. Therefore when a is very large and the function is ill-conditioned, the conjugate gradient direction is almost the steepest descent direction. $\beta^{(1)}$ however, can also be written as follows:

$$\beta^{(1)} = A - 1 \tag{3.3.8}$$

and $s^{(2)}$ is the following:

$$s^{(2)} = -g^{(2)} + \beta^{(1)} s^{(1)}$$

= -2a(a-1) $x_1^{(1)} x_2^{(1)} \frac{K_2}{K_3^2} \begin{bmatrix} -x_2^{(1)} \\ a^2 x_1^{(1)} \end{bmatrix}$

The iteration then continues to give $x^{(3)} = (0, 0)^{T}$ which is the required minimum. But because we are interested in the value of $\beta^{(1)}$ and the direction $s^{(2)}$ it is not necessary to continue beyond this point since there will not be another update.

We shall now consider the case of inexact line searches to see which of the betas makes the quantity $s^{(2)}$ Hs⁽¹⁾ closer to zero and therefore suffers less the effect of inaccuracy in the value of α^* .

b) Inexact Line Search:

Suppose that the line search performed in the first iteration gives $\alpha^*(r) = r\alpha^*$, r > 0. Therefore we obtain:

$$\mathbf{x}^{(2)} = \mathbf{x}^{(1)} + \mathbf{r}\alpha^{*}\mathbf{s}^{(1)} = \frac{(a-1)\mathbf{x}_{1}^{(1)} \mathbf{x}_{2}^{(1)}}{\frac{K_{3}}{K_{3}}} \begin{bmatrix} -\mathbf{x}_{2}^{(1)}\frac{(ra-1)}{(a-1)} \\ a^{2}\mathbf{x}_{1}^{(1)}\frac{(a-r)}{(a-1)} \end{bmatrix} + \frac{1-r}{K_{3}} \begin{bmatrix} a^{3}\mathbf{x}_{1}^{(1)} \\ \mathbf{x}_{2}^{(1)} \end{bmatrix}$$

$$f(x^{(2)}) = K_1 - (2r-r^2)K = f(x^{(1)}) - (2r-r^2)K$$

A necessary condition for the descent property to hold is that $f(x^{(2)}) < f(x^{(1)})$, and because r > 0 and K > 0 we obtain that r must be such that 0 < r < 2. Further, we can exclude the case

r > 1 because in the commonly used backtracking line search algorithms we tend to reduce the step lengths $\alpha^{(k)}$ and therefore r is more likely to be such that $0 < r \leq 1$. On the other hand we have:

$$\dot{g}^{(2)} = \frac{2(a-1)a x_1^{(1)} x_2^{(1)}}{K_3} \begin{bmatrix} -x_2^{(1)} \frac{(ra-1)}{(a-1)} \\ a x_1^{(1)} \frac{(a-r)}{(a-1)} \end{bmatrix} + 2 \frac{(1-r)}{K_3} \begin{bmatrix} a^4 x_1^{(1)^3} \\ x_2^{(1)^3} \end{bmatrix}$$

Note the similarity between the errors that occur in the computation of $x^{(2)}$ and $g^{(2)}$ with inexact line search with respect to the computation of the two vectors with an exact line search. We also have:

$$\|g^{(1)}\|^{2} = 4K_{2}$$
$$\|g^{(2)}\|^{2} = 4K_{2}[Ar^{2} - 2r + 1]$$
$$g^{(2)}g^{(1)} = 4K_{2}(1-r) .$$

We therefore obtain:

$$\beta^{(1)}$$
 (F.R) = Ar² - (2r-1)

and

$$\beta^{(1)}$$
 (P.R) = Ar² - r

where $\beta^{(1)}(F.R)$ and $\beta^{(1)}(P.R)$ denote the formulae (3.1.8) and (3.1.9) respectively. Note that if r = 1 then $\beta(F.R) = \beta(P.R) = A-1$, which is the beta obtained with an exact line search. To simplify the analysis without loss of generality we shall assume that the starting point $x^{(1)}$ is such that $x_1^{(1)} = x_2^{(1)} = c$. Thus we obtain:

$$K_{i} = c^{2}(a^{i}+1), \quad K = c^{2}(a^{2}+1)^{2}/(a^{3}+1), \quad A = \frac{(a^{4}+1)(a^{2}+1)}{(a^{3}+1)^{2}}$$

$$s^{(1)} = -2c \begin{bmatrix} a \\ 1 \end{bmatrix}, \quad g^{(2)} = \frac{2c^{3}}{K_{3}} \left\{ a \begin{bmatrix} 1-ra \\ a(a-r) \end{bmatrix} + (1-r) \begin{bmatrix} a^{4} \\ 1 \end{bmatrix} \right\}$$

$$s^{(2)} = -g^{(2)} + \beta^{(1)}s^{(1)} = -\frac{2ac^{3}}{K_{3}} \begin{bmatrix} 1-ra \\ a^{2}-ra \end{bmatrix} - \frac{2(1-r)c^{3}}{K_{3}} \begin{bmatrix} a^{4} \\ 1 \end{bmatrix} - 2c\beta^{(1)} \begin{bmatrix} a \\ 1 \end{bmatrix}$$

In order to compare the two betas in terms of loss of conjugacy, we shall calculate the quantity $s^{(2)}$ Hs⁽¹⁾ for both betas and see which of the two makes this quantity closer to zero, where H is the Hessian matrix of f. After some arithmetical manipulations we obtain the following:

If
$$\beta^{(1)} = \beta(F.R) = Ar^2 - (2r-1)$$
 then
 $s^{(2)}{}^{T}_{Hs}{}^{(1)} = 0 \Leftrightarrow f^{(F.R)}(r) = (a^4+1)(a^2+1)r^2 - [3(a^3+1)^2 + a^2(a-1)^2]r$
 $+ 2(a^3+1)^2 = 0$

and if

$$\beta^{(1)} = \beta(P.R) = Ar^2 - r$$
 then
 $s^{(2)}{}^T_{H} s^{(1)} = 0 \Leftrightarrow f^{(P.R)}(r) = r^2 - r = 0$.

A study of the variations of $f^{(F,R)}$ and $f^{(P,R)}$ show that $f^{(F,R)}(r) = 0$ for r = 1 and for $r = 2 \frac{(a^3+1)^2}{(a^4+1)(a^2+1)}$ and $f^{(P,R)}(r) = 0$ for r = 0and for r = 1. This study also allows us to draw the following graphs of both $f^{(F,R)}$ and $f^{(P,R)}$. Note that $f^{(P,R)}(r)$ does not depend on the value of a whereas $f^{(F,R)}$ does. The graph for $f^{(F,R)}$

is drawn for a = 1. For a > 1 however, $f^{(F.R)}(r) = 0$ for r = 1

and for r = t where t > 2. We have

 $f_{a=1}^{(F,R)}(r) = r^2 - 3r + 2$, t = 2

Figure 3.3.2

The graphs representing the variations of $f_{a=1}^{(F.R)}(r)$ and $f^{(P.R)}(r)$.

We can clearly see from the Figure that for r between 0 and 1 which is the interval of interest $f^{(P,R)}(r)$ is closer to zero than $f_{a=1}^{(F,R)}(r)$ is, and therefore the quantity $s^{(2)}Hs^{(1)}$ is closer to zero when $\beta(P,R)$ is used. When a > 1 however, $f^{(F,R)}(r)$ will approach 0 as a gets larger but we also know that as a gets larger the two betas will tend towards zero and the method will behave as a steepest descent method. We can therefore conclude that for a > 1 but sufficiently small (not extremely large) the Polak-Ribière method will suffer less the loss of conjugacy due to inexact line searches than the Fletcher-Reeves method would do, and the method of Polak-Ribière is therefore practically preferable.

3.2 GLOBAL CONVERGENCE OF THE POLAK-RIBIERE METHOD.

Although in numerical computations the Polak-Ribière method is generally found to be far more successful than that of Fletcher-Reeves (see the discussion in Sub-Section 3.1.1 and the results in Appendix 2) and although this computational out-performance can somehow be explained theoretically as seen in Sub-Section 3.1.2 above, it has not been possible to establish for the Polak-Ribière method, the global convergence results obtained for the Fletcher-Reeves method by Powell (1983) and by Al-Baali (1985), the proofs of which are given in Section 2 of this Chapter.

However, when some additional conditions are imposed such as "f is a convex function" or "the step-lengths $||x^{(k+1)} - x^{(k)}||$ tend to zero", the global convergence of the Polak-Ribière method with exact line search may be obtained. Powell (1977) notes that inequality (3.3.6) is sufficiently powerful to prove a global convergence theorem, for the Polak-Ribière method, which, in contrast to a similar theorem given by Polak (1971) does not require f to satisfy any convexity conditions. This theorem of Powell's is proved below.

Theorem 3.3.1: (Powell (1977)).

If the level set (3.1.10) is bounded, if f is continuously differentiable and if the step-lengths $||x^{(k+1)} - x^{(k)}||$ tend to zero, then the Polak-Ribière method without restarts achieves the limit (3.2.3).

Proof:

If (3.2.3) is not true there exists a positive constant ε and an integer ℓ such that the bound

$$\|\mathbf{g}^{(\mathbf{k})}\| \geq \varepsilon \tag{3.3.9}$$

holds for all $k \ge \ell$. Since g(x) is continuous and since the step-lengths $||x^{(k+1)} - x^{(k)}||$ tend to zero, there exists an integer $m \ge \ell$ such that the inequality

$$\|g^{(k+1)} - g^{(k)}\| \ge \frac{1}{2} \varepsilon$$
, $k \ge m$ (3.3.10)

is satisfied. Therefore, because the relation

$$\sec \theta^{(k)} \leq 1 + \tan \theta^{(k)}$$
 (3.3.11)

is true for all $\theta^{(k)}$ in [0, $\pi/2$], expression (3.3.6) implies the bound

$$\tan \theta^{(k+1)} \leq \frac{1}{2} (1 + \tan \theta^{(k)}), \quad k \geq m,$$
 (3.3.12)

which is applied recursively to give the inequality

$$\tan \theta^{(k+1)} \leq \frac{1}{2} + \frac{1}{4} + \dots + \left(\frac{1}{2}\right)^{k+1-m} (1 + \tan \theta^{(m)}). \quad (3.3.13)$$

he angle between s^(k) and the steepest descent

Therefore the angle between s^(k) and the steepest descent direction - g^(k) is bounded away from orthogonality. This condition implies that $\|g^{(k)}\|$ tends to zero (Zoutendijk, 1970),

contradicts the hypothesis (3.3.9) and therefor (3.3.9) is false and (3.2.3) must be true.

Before 1983, it was not known whether either of the Fletcher-Reeves or the Polak-Ribière methods provide the limit (3.2.3) for a twice continuously differentiable function with bounded level set from an arbitrary starting point. But, because of condition (3.3.6) and Theorem #, it is straightforward to show for the Polak-Ribière method that if the sequence $\{x^{(k)}, k = 1, 2, ...\}$ converges to a limit x^* say, then $\nabla f(x^*) = 0$. Therefore, one would imagine that establishing (3.2.3) would be easier for the Polak-Ribière method than for that of Fletcher-Reeves. In 1983, however, Powell came out with the surprising negative result. Not only has he shown by a standard method of proof that the limit (3.2.3) is always achieved by the Fletcher-Reeves method (a result that has further been extended by the Al-Baali (1985) for the case of an inexact line search), but he also found that if the Polak-Ribière method is used, then even with exact arithmetic and an exact line search, there exists a twice continuously differentiable function with bounded level set for which the gradient norms $\{\|g^{(k)}\|, k = 1, 2, ...\}$ are bounded away from zero. This counter example of Powell's triggered off the main ideas that lead to the research undertaken in this thesis, and is therefore briefly described below.

It is well known that the limit (3.2.3) is obtained if the directional derivatives:

$$\rho^{(k)} = \frac{s^{(k)} f_{g}^{(k)}}{\|s^{(k)}\| \cdot \|g^{(k)}\|} < 0, \quad k = 1, 2, 3, \dots$$
(3.3.14)

* 3_3_1

are bounded away from zero. Using the arguments developed earlier for the global convergence of the Fletcher-Reeves method from equation (3.2.6) onwards, we deduce that the limit (3.2.3) fails only if $\sum_{k} \rho^{(k)}$ is finite (Zoutendijk, 1970). Therefore noting that the definitions of $\alpha^{(k-1)}$ and $s^{(k)}$ imply the value $\rho^{(k)} = -\|g^{(k)}\| / \|s^{(k)}\|$, the gradient norms $\{\|g^{(k)}\|, k = 1, 2,\}$ are bounded away from zero only if the sequence { $s^{(k)}$, k = 1, 2,} is divergent. In this case, due to the existence of an upper bound on $\{\|g^{(k)}\|$ for $x^{(k)}$ in (3.1.10)}, the direction $s^{(k)}$ tends to be parallel to $s^{(k-1)}$. Therefore to seek counter examples to the limit (3.2.3), it is suitable to consider cases where the points $\{x^{(k)}, k = 1, 2, ...\}$ tend to lie on a straight line, which we take as the first co-ordinate direction in \mathbb{R}^n .

For many finite sequences of distinct points $\{x^{(k)}, k = 1, 2, ..., k\}$ one can find gradients $\{g^{(k)}, k = 1, 2, \dots, l-1\}$ such that the points can be generated by the conjugate gradient method. Specifically, we let $g^{(1)} = x^{(1)} - x^{(2)}$, and, for $k \ge 2$, because of the definitions of $\alpha^{(k-1)}$ and $s^{(k)}$, $g^{(k)}$ has to be a multiple of the vector in the space spanned by $(x^{(k+1)} - x^{(k)})$ and $(x^{(k)} - x^{(k-1)})$ that is orthogonal to $(x^{(k)} - x^{(k-1)})$. To determine the sign and length of $g^{(k)}$, we note that the value (3.1.9) implies the conjugacy condition

$$(x^{(k+1)} - x^{(k)})^{T}(g^{(k)} - g^{(k-1)}) = 0$$
, $k \ge 2$. (3.3.15)
Thus, starting with $g^{(1)} = x^{(1)} - x^{(2)}$, the gradients $g^{(k)}$ for
 $k = 2,3,...$ can usually be found recursively, but the descent
conditions $\{g^{(k)}^{T}(x^{(k+1)} - x^{(k)}) < 0, k = 2,3,..., k-1\}$ may not hold.

Thu

Therefore not all sequences are admissible. Further restrictions on the sequences occur if one lets $\ell \rightarrow \infty$, in particular from the aim of keeping the gradient norms bounded away from zero.

To simplify the analysis Powell (1983) imposes the conditions:

$$\begin{pmatrix} x^{(k+m)} \\ 1 \\ x^{(k+m)} \\ = \theta \\ x^{(k)} \end{pmatrix}$$
 k = 1,2,... (3.3.16)

where m is a small positive integer, $(x)_1$ denotes the first component of x, \hat{x} is the vector in \mathbb{R}^{n-1} whose components are the last (n-1) components of x and θ is a constant from [0, 1]. Thus the distance from $x^{(k)}$ to the first co-ordinate direction tends to zero as $k \rightarrow \infty$. Having chosen m and n, there are only a finite number of parameters in the sequence $\{x^{(k)}, k = 1, 2, ...\}$. One can then express the conditions of consistency with the conjugate gradient method as inequality constraints on the parameters and investigate whether the inequalities have a solution. Powell (1983) then reports some interesting cases for n = 2 and n = 3. For n = 3 he finds that the gradients can stay bounded away from zero if one gives up the second derivative continuity of the objective function. Then, by letting m = 8, he shows that one can preserve the second derivative continuity if one modifies (3.1.3) by allowing $\alpha^{(k)}$ to be any local minimum of $\phi(\alpha) = f(x^{(k)} + \alpha s^{(k)})$ that satisfies $\phi(\alpha^{(k)}) < \phi(0)$. This is an important case because in practice one can usually accept any local minimum that sufficiently reduces the objective function. Finally by letting n = 3 and m = 6 Powell (1983) finds that the gradients $\{g^{(k)}, k = 1, 2, \dots\}$ can remain bounded away from zero when all the conditions that have been stated are satisfied.

Powell's two-variable examples are relevant not only to the conjugate gradient methods but also to all variable metric algorithms in Broyden's linear family that make exact line searches (see Fletcher (1980), for example). The reason is that condition (3.3.15) and $s^{(k)^T} g^{(k)} < 0$ define the direction $(x^{(k+1)} - x^{(k)})$ when there are only two variables. Therefore the D.F.P. and B.F.G.S. algorithms may fail to converge, if the condition on the step length $\alpha^{(k)}$ is only that it be a local minimum of the function $\phi(\alpha) \quad \alpha \ge 0$ that satisfies $\phi(\alpha^{(k)}) < \phi(0)$. An important consequence of this remark is that if a proof of convergence of one of these algorithms for general twice continuously differentiable functions could be found, then the proof would depend on line search conditions that are stronger than one usually assumes. Thomson (1977) gives other examples of non convergence for the D.F.P algorithm but he allows the objective function to have first derivative discontinuities.

4. IMPROVEMENTS ON THE CONJUGATE GRADIENT METHOD.

4.1 A Conjugate Direction Method by D. Le (1985).

D. Le (1985) describes a new unconstrained optimization procedure that employs conjugate directions and requiring only three n-dimensional vectors. In common with conjugate gradient methods, this method generates a sequence of search directions $s^{(k)}$ that are linear combinations of $-g^{(k)}$ and $s^{(k-1)}$. This method can be described as follows:

Given a starting point $x^{(1)}$, let $s^{(1)} = -g^{(1)} / ||g^{(1)}||$,

the vector norms being Euclidean.

For $k \ge 1$, let $x^{(k+1)} = x^{(k)} + \alpha^{(k)} s^{(k)}$

where $\alpha^{(k)}$ is the minimizer of the function $\phi(\alpha) = f(x^{(k)} + \alpha s^{(k)})$.

If
$$g^{(k+1)} = 0$$
, stop; otherwise let

$$\omega^{(k+1)} = x^{(k+1)} + \beta^{(k+1)} (-g^{(k+1)} / ||g^{(k+1)}||) ,$$

$$z^{(k+1)} = \omega^{(k+1)} + \gamma^{(k+1)} s^{(k)} , \text{ and}$$

$$s^{(k+1)} = (z^{(k+1)} - x^{(k+1)}) / ||z^{(k+1)} - x^{(k+1)}|| ,$$

where $\gamma^{(k+1)}$ is the minimizer of the function $\phi(\gamma) = f(\omega^{(k+1)} + \gamma s^{(k)})$, and $\beta^{(k+1)}$ is determined by the following procedure:

Let $\lambda \equiv \beta$, $v \equiv x$ and $u \equiv -g/|g|$

(1) Let
$$\lambda_0 = 0$$
, $\lambda_1 = \lambda_0$, $\lambda_2 = \sigma$ and $\xi = \psi(0)$
where $\psi(\lambda) = f(v+\lambda u)$.

(2) Fit a parabola
$$p(\lambda)$$
 to $\psi(\lambda)$ using $\psi(0)$, $\psi'(0)$ and $\psi(\lambda_2)$.

- (3) Let λ̂ be the point such that p(λ̂) = p(0) = ψ(0) and λ̂ ≠ 0.
 Care should be taken to avoid overflow in solving p(λ) = ψ(0) for λ̂. If two solutions exist that are both non-zero, the larger value is taken for λ̂.
- (4) If $\lambda_1 < \hat{\lambda} \le 4\sigma$ and $p(\lambda)$ is convex, then accept $\hat{\lambda}$ as the required solution for $\beta^{(k)}$; otherwise let $\lambda_0 = \lambda_1$, $\lambda_1 = \lambda_2$, $\sigma = 4\sigma$, $\lambda_2 = \sigma$ and fit a parabola $p(\lambda)$ through $\psi(\lambda_0)$, $\psi(\lambda_1)$, $\psi(\lambda_2)$ and repeat step (3).

The value o used in this procedure is the initial stepsize in the

line search. D. Le takes $\sigma = 0.05$

Apart from its use in $\omega^{(k+1)}$ above, $\beta^{(k+1)}$ also plays the important role of setting the initial stepsize for subsequent line searches to determine $\gamma^{(k+1)}$, $\alpha^{(k+1)}$ and $\beta^{(k+2)}$. The chosen value of $\beta^{(k+1)}$ is usually larger than that required to minimize f(x) along the steepest descent direction - $g^{(k+1)}$ and the motivation for such a choice is that it could help to speed up convergence by cutting corners over curved ridges. D. Le (1985) has experimentally examined several alternatives on the choice of $\beta^{(k)}$ and has found that both very small and very large values of $\beta^{(k)}$ are undesirable. Small values of $\beta^{(k)}$ tend to produce search directions s^(k) close to the steepest descent direction - $g^{(k)}$ which usually results in slower speed of convergence. Moreover, as $\beta^{(k)}$ is used as initial stepsize in subsequent line searches, a small value of $\beta^{(k)}$ means more steps and thus more function evaluations required to bracket the local minimum. Although large values of $\beta^{(k)}$ can sometimes produce spectacular results by side-stepping ridges, it usually requires more refining steps at the final stage of each line search and there is also a high probability of overstepping the local minimum to an unwanted nearby one. D. Le (1985) has also tested this method for computational efficiency and stability on a large set of test functions and compared them with numerical data of other major methods. Although the comparison showed that the method possesses strong superiority over other existing conjugate gradient methods on all problems and can out-perform or is at least as efficient as quasi-Newton methods on many tested problems, our feeling is that because the comparison approach adopted relies

on the literature for numerical results of other methods, it (the approach) presents the major drawback that the results reported for different methods as compiled from different authors' work are not fairly comparable due to such factors as the difference in computers and compiler systems, single or double precision, different line search methods, different stopping criteria, etc.

4.2 An Angle Test as a Restart Criterion for C.G. Algorithms by Shanno (1985).

Shanno (1985) gives an angle test procedure for determining when to restart conjugate gradient methods with a steepest descent direction. The test is based on guaranteeing that the cosine of the angle between the search direction and the negative gradient is within a constant multiple of the cosine of the angle between the Fletcher-Reeves search direction and the negative gradient. This guarantees convergence for the Fletcher-Reeves method is known to converge. This procedure is of importance to what will follow in Chapter 5 and is therefore described below.

Under the assumption that exact line searches are performed, for all conjugate gradient methods we have

$$\cos^{2}(\theta^{(k)}) = \|g^{(k)}\|^{2} / \|s^{(k)}\|^{2}$$
(3.4.1)

and

$$\|\mathbf{s}^{(k)}\|^{2} = \|\mathbf{g}^{(k)}\|^{2} + \beta^{(k-1)}\|\mathbf{s}^{(k-1)}\|^{2} . \qquad (3.4.2)$$

For $\beta^{(k-1)}$ taken to be the Fletcher-Reeves update, from (3.2.4) we obtain

$$\|\mathbf{s}^{(k)}\|^{2} = \sum_{\ell=1}^{k} \|\mathbf{g}^{(k)}\|^{4} / \|\mathbf{g}^{(\ell)}\|^{2}$$
(3.4.3)
and because $\|g^{(k)}\|$ is bounded above and if $\|g^{(k)}\|$ is also bounded away from zero we obtain:

$$\| s^{(k)} \| \leq ck$$
 (3.4.4)

and hence from (3.4.1), $\sum_{k} \cos^{2}(\theta^{(k)})$ is divergent. (See Powell's proof for the convergence of the Fletcher-Reeves method in Section 2). It is immediately obvious that if $\sum_{k} \cos^{2}(\theta^{(k)})$ is divergent then for any $\tau > 0$, $\tau \sum_{k} \cos^{2}(\theta^{(k)})$ is divergent. Now, by substituting (3.4.3) into (3.4.1), we obtain:

$$\cos^{2}(\theta^{(k)}) = \frac{1}{\|g^{(k)}\|^{2} \sum_{\substack{k=1 \\ k=1}}^{k} \|g^{(k)}\|^{-2}} . \qquad (3.4.5)$$

Thus for any $\tau > 0$, we define $\gamma^{(k)}$ by

$$\gamma^{(k)^{2}} = \frac{\tau}{\|g^{(k)}\|^{2} \sum_{\ell=1}^{k} \|g^{(\ell)}\|^{-2}}$$
 (3.4.6)

Shanno's proposed algorithm is then, to calculate a trial $\hat{s}^{(k)}$ by any desired conjugate gradient formula, then calculate:

$$\cos^{2}(\hat{\theta}^{(k)}) = (g^{(k)^{T}} \hat{s}^{(k)})^{2} / \|g^{(k)}\|^{2} \cdot \|\hat{s}^{(k)}\|^{2} . \qquad (3.4.7)$$

The final search direction s^(k) is chosen by:

$$s^{(k)} = \begin{cases} \hat{s}^{(k)} & \text{if } \cos^{2}(\hat{\theta}^{(k)}) \ge \gamma^{(k)^{2}} \\ & & \\ -g^{(k)} & \text{if } \cos^{2}(\hat{\theta}^{(k)}) < \gamma^{(k)^{2}} \end{cases} .$$
(3.4.8)

Thus $\gamma^{(k)}$ is used to determine when to fully restart a conjugate gradient search in the direction of the negative gradient.

This algorithm can easily be shown to converge to a stationary point. By (3.4.6), $\tau \leq 1$ implies $\gamma^{(k)^2} \leq 1$. If $s^{(k)} = \hat{s}^{(k)}$, by (3.4.8) $\cos^2(\theta^{(k)}) = \cos^2(\hat{\theta}^{(k)}) \geqslant \gamma^{(k)^2}$. If $s^{(k)} = -g^{(k)}$, $\cos^2(\theta^{(k)}) = 1$. Hence $\cos^2(\theta^{(k)}) \geqslant \gamma^{(k)^2}$ for all k and therefore $\sum_k \cos^2(\theta^{(k)})$ diverges by the divergence of $\sum_k \gamma^{(k)^2}$. Thus by Zoutendijk's theorem (1970), the sequence $x^{(k)}$ converges.

An important feature of choosing $s^{(k)}$ by (3.4.8) is that for τ appropriately chosen, once the iterative sequence approaches the minimum sufficiently closely, restarts will not occur. This follows directly from the fact that once the minimum has been approached sufficiently closely, terms of higher order than quadratic have negligible influence on the search direction. As at least two trial points are evaluated using quadratic interpolation along each search direction, all conjugate gradient algorithms reduce to essentially the Fletcher-Reeves algorithm. Thus asymptotically, the rate of convergence is not affected.

The identity (3.4.1) is true for all conjugate gradient methods provided exact line searches are performed. However this is hardly ever done in practice. When $s^{(k)}$ is chosen by (3.1.7) for example, we have:

$$(s^{(k)}{}^{T}g^{(k)})^{2} = (g^{(k)}{}^{T}g^{(k)})^{2} - 2\beta^{(k-1)}s^{(k-1)} + \beta^{(k)}{}^{2}(g^{(k)}{}^{T}s^{(k-1)})^{2}$$

(3.4.9)

With inexact line searches, $(g^{(k)T}s^{(k-1)})$ may be substantially different from zero. Thus setting $\tau = 1$ could appear too restrictive. Shanno used the values $\tau = 0.1$, $\tau = 0.01$ and $\tau = 0$, and from his results noted that τ in the range 0.01 $\leq \tau \leq 0.1$ should be adequate in most cases.

Shanno (1985) suggests that because the counter-example of Powell (1983) showing cycling of the Polak-Ribière method casted doubts upon whether a global convergence proof for quasi-Newton methods will ever be found, a test similar to (3.4.6) could be implemented for these methods as well, since in a region surrounding the optimum where f(x) behaves essentially as a quadratic, conjugate gradient and quasi-Newton methods produce the same sequence of points.

4.3 Avoiding Negative Updates of the Polak-Ribière Method.

Powell (1985) gives an alternative explanation of the computational superiority of the Polak-Ribière method over that of Fletcher-Reeves, to that discussed in Section 3.1.2 of this Chapter. He supposes that the k^{th} iteration of a conjugate gradient method has made a change $||x^{(k+1)} - x^{(k)}||$ that is much smaller than the step that would have been taken by the steepest descent algorithm and investigates whether the next iteration can be as bad. A relatively small value of $||x^{(k+1)} - x^{(k)}||$ occurs only if the angle $\theta^{(k)}$ between $s^{(k)}$ and $-g^{(k)}$ is close to $\pi/2$. Therefore, because the exact line search along $s^{(k-1)}$ and the definition of $s^{(k)}$ imply the value

$$\cos \theta^{(k)} = \|g^{(k)}\| / \|s^{(k)}\|$$

we must have $\|s^{(k)}\| \gg \|g^{(k)}\|$, and we wish to avoid $\|s^{(k+1)}\| \gg \|g^{(k+1)}\|$. Now, the relatively small value of $\|x^{(k+1)} - x^{(k)}\|$ gives $\|g^{(k+1)}\| \gg \|g^{(k)}\|$, so the Fletcher-Reeves and the Polak-Ribière formulae yield $\beta^{(k)} \approx 1$ and $|\beta^{(k)}| \ll 1$ respectively. Further using the line search along $s^{(k)}$ being exact and the definition of $s^{(k+1)}$, we deduce the relation:

$$\| \mathbf{s}^{(k+1)} \| = \left\{ \| \mathbf{g}^{(k+1)} \|^{2} + \beta^{(k)^{2}} \| \mathbf{s}^{(k)} \|^{2} \right\}^{\frac{1}{2}} . \qquad (3.4.10)$$

It then follows that the Fletcher-Reeves formula gives $\|s^{(k+1)}\| \approx \|s^{(k)}\|$, but the Polak-Ribière formula gives $\|s^{(k+1)}\| << \|s^{(k)}\|$ as required. The crucial difference between the two formulae for $\beta^{(k)}$ is that, if the term $\beta^{(k)} s^{(k)}$ dominates the term - $g^{(k+1)}$ in the equation defining $s^{(k+1)}$, (3.1.7), then in the Fletcher-Reeves methods, the directions $s^{(k+1)}$ and $s^{(k)}$ are nearly the same, but these directions can be almost opposite in the Polak-Ribière method due to $\beta^{(k)} < 0$. Powell (1985) therefore suggests to avoid the use of negative updates when using the Polak-Ribière algorithm by using the following value instead:

$$\beta^{(k)} = \max\left\{0, g^{(k+1)^{T}}(g^{(k+1)} - g^{(k)}) / \|g^{(k)}\|^{2}\right\}, \quad (3.4.11)$$

that he reckons may be more useful than those of Fletcher-Reeves and Polak-Ribiere.

In this thesis we have implemented this formula (3.4.11) in a conjugate gradient routine and tested the resulting method on all the test problems discussed herein. The results given in Appendices 2 and 3 show that this method does indeed out-perform both the Fletcher-Reeves and the Polak-Ribière method on a large number of test problems. The overall comparison results shown in Appendix 3, Table (3.3), show that this algorithm obtains the required minimo. of all the 182 cases considered in 52%, 50% and 52% less than the Fletcher-Reeves algorithm and in 11%, 10% and 12% less than the Polak-Ribière algorithm, in terms of number of iterations (NI), number of function evaluations (NF) and index of computational labour (NC) respectively, the index of computational labour being defined as NC = NF + n.NG, where n is the number of variables and NG the number of gradient evaluations. This idea being computationally attractive, we thought of trying to use both the Polak-Ribière and the Fletcher-Reeves formulae for $\beta^{(k)}$ on one algorithm in an attempt to try and approach the method to fit the convergence proofs of the Fletcher-Reeves method. As a first attempt, we tried to replace each negative update of the Polak-Ribière algorithm by a Fletcher-Reeves one which is always positive. This resulted in the following hybrid algorithm: ORIG1 :

Use a conjugate gradient algorithm where the update $\beta^{(k)}$ is defined as follows:

$$\beta^{(k)} = \begin{cases} \beta^{(k)}(P.R) & \text{if } \beta^{(k)}(P.R) > 0 \\ \\ \beta^{(k)}(F.R) & \text{if } \beta^{(k)}(P.R) \leq 0 \end{cases}$$

where $\beta^{(k)}(F.R)$ and $\beta^{(k)}(P.R)$ denote the updates of the Fletcher-Reeves and Polak-Ribière methods respectively. This hybrid algorithm ORIG1 was also tested on all the test problems discussed in this thesis and proved to be computationally preferable to both the Fletcher-Reeves and Polak-Ribière algorithm. The overall comparison results shown in Appendix 3, Table (3.4) show that ORIG1 obtains the required minima in 49%, 47% and 49% less than the Fletcher-Reeves and 4%, 4% and 6% less than the Polak-Ribière algorithm in terms of the NI, NF and NC respectively where NI, NF and NC are as defined above. It was however, slightly less efficient than the algorithm using formula (3.4.11) to compute $\beta^{(k)}$.

(3.4.12)

As a second attempt, it was found that including the Hestenes and Stiefel update in the hybrid was also useful, although using the Hestenes-Stiefel $\beta^{(k)}$ on its own has failed on many occasions to converge and therefore its results are not included here. The new hybrid algorithm ORIG2 using the three formulae together in an conjugate gradient algorithm computes its update as follows:

1°/ If
$$\beta^{(k)}(H.S) > 0$$
, $\beta^{(k)} = \beta^{(k)}(H.S)$, return
otherwise go to step 2°

2°/ If $\beta^{(k)}(P.R) > 0$, $\beta^{(k)} = \beta^{(k)}(P.R)$, return otherwise go to step 3°

$$3^{\circ}/\beta^{(k)} = \beta^{(k)}(F.R)$$
.

Here $\beta^{(k)}(F.R)$ and $\beta^{(k)}(P.R)$ are as defined above and $\beta^{(k)}(H.S)$ denotes the update $\beta^{(k)}$ of Hestenes and Stiefel. This hybrid algorithm ORIG2 was tested on all the test problems discussed in this thesis and proved to be computationally preferable to all the Fletcher-Reeves, Polak-Ribière, the algorithm using Powell's suggestion of using formula (3.4.11) and to ORIG1. The overall comparison results given in Appendix 3, Table (3.5) show the following improvement percentages over the Fletcher-Reeves and the Polak-Ribière respectively: 52%, 50%, 52% and 10%, 10%, 12% in turns of NI, NF and NC respectively.

These encouraging computational results lead to thought on how to combine the attractive computational performance of the Polak-Ribière method and the desirable theoretical features of the Fletcher-Reeves in order to come out with a hybrid algorithm that has the two properties. The investigation of this idea and the resulting hybrid algorithms make the subject of the following two chapters.

Chapter 4

Globally Convergent Hybrid Conjugate Gradient Methods

1. INTRODUCTION.

For general twice continuously differentiable functions with bounded level sets (3.1.10), the Fletcher-Reeves method is shown to achieve the limit (3.2.3), when either exact line searches (Powell (1983)) or inexact line searches satisfying certain standard conditions (Al-Baali (1985)) are used, without any convexity assumptions, (see Chapter 3 - Section 2).

Although in numerical computations, the Polak-Ribière method is generally far more successful than that of Fletcher-Reeves, as can be seen from the results tables reported in Appendices 2 and 3, and as can theoretically be explained as seen in Chapter 3, subsection 3.1.2, it has not been possible to establish these global convergence results for the Polak-Ribière method. Furthermore, Powell (1983) also shows that if the Polak-Ribière is used, then even with exact line searches and exact arithmetic, there exist twice continuously differentiable functions with bounded level sets (3.1.10) for which the gradient norms { $\|g^{(k)}\|$, k = 1,2,...} are bounded away from zero.

This has consequently 1 ed to thoughts on how to combine the desirable computational aspects of the Polak-Ribière method and the useful theoretical features of the Fletcher-Reeves method in an attempt to construct some efficient hybrid algorithms that are globally convergent. The purpose of this chapter is then to show how the proofs of Powell (1983) and the Al-Baali (1985) can be used to guarantee global convergence of conjugate gradient algorithms, that are to be constructed in this thesis, which are hybrids between the Polak-Ribière and the Fletcher-Reeves updates.

2. A NEW HYBRID ALGORITHM: HYBRID 1.

2.1 Construction of the Algorithm.

The idea of avoiding the use of negative updates of the Polak-Ribière method and replacing them with updates of the Fletcher-Reeves, that resulted in the hybrid algorithm ORIG1 discussed in Chapter 3 subsection 4.3, has proved to be computationally efficient but does not ensure the global convergence of the obtained algorithm. However, we find that if the Polak-Ribière $\beta^{(k)}$ are restricted to remain non-negative and at the same time less than or equal to the Fletcher-Reeves $\beta^{(k)}$, then the convergence proofs given by Powell (1983) and by Al-Baali (1985) both apply to the Polak-Ribière method also, but these restrictions are unfortunately not always satisfied.

Remark 1:

Let $\beta^{(k)}(F.R)$ and $\beta^{(k)}(P.R)$ denote the betas satisfying (3.1.8) and (3.1.9) respectively. We then have

$$\beta^{(k)}(P.R) = \beta^{(k)}(F.R) - g^{(k+1)^{T}} g^{(k)} / ||g^{(k)}||^{2}$$
 (4.2.1)

If $\beta^{(k)}(P.R)$ were always non-negative, we would have

$$\beta^{(k)}(P.R) \ge 0 \Rightarrow \beta^{(k)}(F.R) \ge g^{(k+1)^{T}} g^{(k)} ||g^{(k)}||^{2}$$
$$\Rightarrow ||g^{(k+1)}||^{2} \ge g^{(k+1)^{T}} g^{(k)}$$

and if $\beta^{(k)}(P.R)$ were always less than or equal to $\beta^{(k)}(F.R)$ we would have

$$\beta^{(k)}(P.R) \leq \beta^{(k)}(F.R) \Rightarrow -g^{(k+1)^{T}} g^{(k)} / \|g^{(k)}\|^{2} \leq 0$$
$$\Rightarrow g^{(k+1)^{T}} g^{(k)} \geq 0 \quad . \tag{4.2.2}$$

Therefore the restrictions that we would like to impose on the Polak-Ribière beta will hold if

$$0 \leq g^{(k+1)^{T}} g^{(k)} \leq ||g^{(k+1)}||^{2} . \qquad (4.2.3)$$

As a consequence of this remark, we suggest the use of a hybrid conjugate gradient algorithm, Hybrid 1, using formula (3.1.9) whenever condition (4.2.3) is satisfied and formula (3.1.8) otherwise. In other words we define $\beta^{(k)}$ in (3.1.7) as follows:

$$\beta^{(k)} = \begin{cases} g^{(k+1)^{T}}(g^{k+1}) - g^{(k)} / \|g^{(k)}\|^{2} & \text{if (4.2.3) is true} \\ \|g^{(k+1)}\|^{2} / \|g^{(k)}\|^{2} & \text{otherwise} \end{cases}$$

$$(4.2.4)$$

It is also possible to use resetting as in straight-forward Fletcher-Reeves and Polak-Ribière methods, but this does not affect the validity of the proofs that follow.

2.2 Descent Property and Global Convergence of Hybrid 1.

2.2.1 Exact Line Search.

We have already shown (3.2.2) that if the line search is exact then a descent property holds on all iterations for both Fletcher-Reeves and Polak-Ribière methods and therefore it is obvious that it also holds for the proposed hybrid method. Let us now assume that f(x) is twice continuously differentiable, that the level set (3.1.10) is bounded and that an exact line search is performed at each iteration of the algorithm using formula (4.2.4). We ask whether these conditions are sufficient to provide the limit (3.2.3) for the proposed hybrid method.

Theorem 4.2.1:

If f(x) is twice continuously differentiable, if the level set (3.1.10) is bounded and if an exact line search is performed at each iteration, then the limit (3.2.3) is achieved by Hybrid 1.

Proof:

The method of proof is the same as that given by Powell (1983) for the global convergence of the Fletcher-Reeves method.

It is well known that the limit (3.2.3) is obtained if the directional derivatives

$$d^{(k)} = s^{(k)^{T}} g^{(k)} / (\|s^{(k)}\| \cdot \|g^{(k)}\|) < 0$$
(4.2.5)

are bounded away from zero. Specifically, by letting all vector norms be Euclidean, and by letting Ω be an upper bound on the induced matrix norms $\{ \| \nabla^2 f(x) \|$, for x in the level set (3.1.10) $\}$, we obtain the relation:

$$f(x) \leq f(x^{(k)}) + (x-x^{(k)})^T g^{(k)} + \frac{1}{2} \Omega ||x-x^{(k)}||^2$$
 (4.2.6)

for any x in the level set (3.1.10). Because $x^{(k+1)}$ is in the level set (3.1.10) (descent property), relation (4.2.6) is also true when we replace x by $x^{(k+1)}$. Therefore

$$E(x^{(k+1)}) \leq f(x^{(k)}) + (x^{(k+1)} - x^{(k)})^{T} g^{(k)} + \frac{1}{2} \Omega \|x^{(k+1)} - x^{(k)}\|^{2}$$

But
$$x^{(k+1)} = x^{(k)} + \alpha^{(k)} s^{(k)} \Rightarrow x^{(k+1)} - x^{(k)} = \alpha^{(k)} s^{(k)}$$

where $\alpha^{(k)}$ is such that (3.1.3) is satisfied. It follows that:

$$f(x^{(k+1)}) \leq \min_{\alpha} \left[f(x^{(k)}) + \alpha s^{(k)^{T}} g^{(k)} + \frac{1}{2} \Omega \alpha^{2} \|s^{(k)}\|^{2} \right]. \quad (4.2.8)$$

The minimum value of the right hand side of (4.2.8) with respect to α is obtained when

$$\alpha = \alpha^{(k)} = -\frac{s^{(k)} g^{(k)}}{\Omega \| s^{(k)} \|^2} . \qquad (4.2.9)$$

By substituting (4.2.9) into (4.2.8) and after some simple arithmetic considerations we get

$$f(x^{(k+1)}) \leq f(x^{(k)}) - d^{(k)^2} \frac{\|g^{(k)}\|^2}{2\Omega}$$
 (4.2.10)

Thus, because f(x) is bounded below $\sum_{k} d^{(k)} \|g^{(k)}\|^{2}$ is a convergent series. Hence condition (3.2.3) fails only if

$$\sum_{k} d^{(k)}$$
 (4.2.11)

is convergent (Zoutendijk (1970)).

On the other hand, from the definition of $s^{(k)}$ and exact line search, we deduce the equation

$$\| s^{(k)} \|^{2} = \| g^{(k)} \|^{2} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2}$$
$$= \sum_{\ell=1}^{k} \left\{ \frac{k^{-1}}{\prod_{j=\ell}^{n} \beta^{(j)}} \right\} \| g^{(\ell)} \|^{2}.$$

Since every beta calculated by Hybrid 1 is less than or equal to $\|g^{(k)}\|^2 / \|g^{(k-1)}\|^2$, it follows that:

$$\|s^{(k)}\|^{2} \leq \sum_{\ell=1}^{k} \|g^{(k)}\|^{4} / \|g^{(\ell)}\|^{2} \qquad (4.2.12)$$

Further we recall that $\|g^{(k)}\|$ is bounded above because $x^{(k)}$ is in the level set (3.1.10). Therefore if (3.2.3) is not true then:

$$\| s^{(k)} \|^2 \leq kc$$
 (4.2.13)

where c is a positive constant. From the definition of $\alpha^{(k-1)}$ and $s^{(k)}$ it follows that $d^{(k)} = - \|g^{(k)}\| / \|s^{(k)}\|$ and therefore the sum (4.2.11)

$$\sum_{k} d^{(k)^{2}} = \sum_{k} \|g^{(k)}\|^{2} / \|s^{(k)}\|^{2}$$
(4.2.14)

would be divergent, which would contradict the fact that $\sum_{k} d^{(k)} \|g^{(k)}\|^{2}$ is convergent established above. Since this contradiction arises from the assumption that (3.2.3) is not true then the limit (3.2.3) must be achieved and hence Hybrid 1 using $\beta^{(k)}$ to satisfy (4.2.4) is globally convergent when exact line searches are performed.

2.2.2 Inexact Line Search.

In what follows, Hybrid 1 is shown to have the descent property and to be globally convergent when an inexact line search is performed. The methods of proof to be followed here are the same as those given by Al-Baali (1985).

Theorem 4.2.2:

If an $\alpha^{(k)}$ is calculated which satisfies (3.1.4) with $\sigma \in (0, \frac{1}{2}]$ for all k such that $g^{(k)} \neq 0$, then the descent property (3.1.6) for Hybrid 1, holds for all such k.

Proof:

The method of proof is to show by induction that the inequalities:

$$-\sum_{j=0}^{k-1} \sigma^{j} \leq \frac{g^{(k)}}{\|g^{(k)}\|^{2}} \leq -2 + \sum_{j=0}^{k-1} \sigma^{j} \qquad (4.2.15)$$

hold for all k such that $g^{(k)} \neq 0$. It will then follow inductively that the descent property (3.1.6) holds for all such k.

For k = 1, (4.2.15) is clearly satisfied. Now assume that (4.2.15) is true for any $k \ge 1$. Since

$$\sum_{j=0}^{k-1} \sigma^{j} < \sum_{j=0}^{\infty} \sigma^{j} = \frac{1}{1-\sigma} , \qquad (4.2.16)$$

it is clear that the right hand side of (4.2.15) is negative for any σ in (0, $\frac{1}{2}$] and hence the descent property (3.1.6) is satisfied on iteration k. It follows from the definition of s^(k+1) (3.1.7) that:

$$\frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^2} = -1 + \beta^{(k)} \frac{g^{(k+1)} s^{(k)}}{\|g^{(k+1)}\|^2}. \qquad (4.2.17)$$

If $\beta^{(k)}$ takes the value (3.1.8), the proof is given by Al-Baali (1985). We shall then concentrate here on the case where $\beta^{(k)}$ takes the value (3.1.9). In this case (4.2.17) becomes:

$$\frac{g^{(k+1)^{T}} g^{(k+1)}}{\|g^{(k+1)}\|^{2}} = -1 + \frac{(\|g^{(k+1)}\|^{2} - g^{(k+1)^{T}} g^{(k)})}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k+1)}\|^{2}}$$
$$= -1 + \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k)}\|^{2}} \left(1 - \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k+1)}\|^{2}}\right).$$

Since we are using $\beta^{(k)}$ that satisfies (3.1.9), by definition of the algorithm we have $0 \leq g^{(k+1)T} g^{(k)} \leq ||g^{(k+1)}||^2$. It then follows that:

$$0 \leq a = 1 - \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k+1)}\|^{2}} \leq 1 \quad . \tag{4.2.18}$$

Therefore:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} = -1 + a \frac{g^{(k+1)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}}$$
(4.2.19)

with $0 \le a \le 1$. Using (3.1.4), (3.1.6) and (4.2.19) we get:

$$-1 + a\sigma \frac{g^{(k)} \frac{1}{s} \frac{g^{(k)}}{\|g^{(k)}\|^{2}}}{\|g^{(k+1)}\|^{2}} \leq \frac{g^{(k+1)} \frac{1}{s} \frac{g^{(k+1)}}{\|g^{(k+1)}\|^{2}}}{\|g^{(k+1)}\|^{2}} \leq -1 - a\sigma \frac{g^{(k)} \frac{1}{s} \frac{g^{(k)}}{\|g^{(k)}\|^{2}}}{\|g^{(k)}\|^{2}}.$$
(4.2.20)
using the induction hypothesis (4.2.15), the fact that

Then using the induction hypothesis (4.2.15), the fact that $0 \le a \le 1$ and (4.2.20)

$$-\sum_{j=0}^{k} \sigma^{j} = -1 - \sigma \sum_{j=0}^{k-1} \sigma^{j} \leq -1 - a \sigma \sum_{j=0}^{k-1} \sigma^{j} \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}}$$
$$\leq -1 + a \sigma \sum_{j=0}^{k-1} \sigma^{j} \leq -1 + \sigma \sum_{j=0}^{k-1} \sigma^{j} = -2 + \sum_{j=0}^{k} \sigma^{j}$$
$$\Rightarrow -\sum_{j=0}^{k} \sigma^{j} \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -2 + \sum_{j=0}^{k} \sigma^{j}$$

which is (4.2.15) with k replaced by k+1. Thus the induction is complete.

A consequence of this descent property is the following global convergent result.

Theorem 4.2.3:

If the set (3.1.10) is bounded, if f(x) is twice continuously differentiable, and if $\alpha^{(k)}$ is any value satisfying (3.1.4) and (3.1.5) with $\rho < \sigma < \frac{1}{2}$, then equation (3.2.3) holds for Hybrid 1.

Proof:

It is shown in Theorem 4.2.2 that the descent property (3.1.6) holds for $\sigma \in (0, \frac{1}{2}]$, so from (3.1.4), (4.2.15) and (4.2.16), it follows that:

$$|g^{(k)}{}^{T} s^{(k-1)}| \leq -\sigma g^{(k-1)}{}^{T} s^{(k-1)} \leq \frac{\sigma}{1-\sigma} ||g^{(k-1)}||^{2}$$
. (4.2.21)

Then from the definition of s^(k) we have:

$$\| s^{(k)} \|^{2} = \| g^{(k)} \|^{2} - 2\beta^{(k-1)} g^{(k)^{T}} s^{(k-1)} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2}.$$

Using (4.2.21) we obtain:

$$\| s^{(k)} \|^{2} \leq \| g^{(k)} \|^{2} + \frac{2\sigma}{1-\sigma} \beta^{(k-1)} \| g^{(k-1)} \|^{2} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2}$$

Since

$$\beta^{(k-1)} \leq \frac{\|\underline{g}^{(k)}\|^2}{\|\underline{g}^{(k-1)}\|^2} \quad \text{it follows that:}$$

$$\| \mathbf{s}^{(k)} \|^{2} \leq \| \mathbf{g}^{(k)} \|^{2} + \frac{2\sigma}{1-\sigma} \| \mathbf{g}^{(k)} \|^{2} + \beta^{(k-1)^{2}} \| \mathbf{s}^{(k-1)} \|^{2}$$

$$\leq \left(\frac{1+\sigma}{1-\sigma}\right) \| \mathbf{g}^{(\mathbf{k})} \|^2 + \beta^{(\mathbf{k}-1)^2} \| \mathbf{s}^{(\mathbf{k}-1)} \|^2$$

and it follows by induction that

$$\| s^{(k)} \|^{2} \leq \left(\frac{1+\sigma}{1-\sigma} \right) \| g^{(k)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2} .$$
 (4.2.22)

Now, if (3.2.3) is not true, then there exists a constant ε say, such that

$$\|g^{(k)}\| \ge \varepsilon \ge 0$$
 for all k. (4.2.23)

But $g^{(k)}$ is also bounded above in the level set (3.1.10) and so from (4.2.22) we have:

$$\| s^{(k)} \|^2 < c_1 k$$
 (4.2.24)

where c_1 is a positive constant. From (4.2.15) and (4.2.16), it follows that:

$$\cos(\theta^{(k)}) \ge \left(\frac{1-2\sigma}{1-\sigma}\right) \frac{\|g^{(k)}\|}{\|s^{(k)}\|}$$
(4.2.25)

where

$$\cos(\theta^{(k)}) = -g^{(k)^{T}} s^{(k)} / (\|g^{(k)}\| \cdot \|s^{(k)}\|) \qquad (4.2.26)$$

and $\theta^{(k)}$ is the angle between $s^{(k)}$ and the steepest descent direction - $g^{(k)}$. Because $\sigma < \frac{1}{2}$, from (4.2.24) and (4.2.25) we obtain:

$$\sum_{k} \cos^{2}(\theta^{(k)}) \ge \left(\frac{1-2\sigma}{1-\sigma}\right)^{2} \sum_{k} \|g^{(k)}\|^{2} / \|s^{(k)}\|^{2}$$
$$\ge c_{2} \sum_{k} k^{-1}$$
(4.2.27)

where c_2 is a positive constant. Hence the series $\sum_k \cos^2 \theta^{(k)}$ diverges. However it is possible to contradict this result using the line search conditions. If Ω is an upper bound on $\| \nabla^2 f(x) \|$, where x is any point in the level set (3.1.10), then we have:

$$g^{(k+1)^{T}} s^{(k)} \leq g^{(k)^{T}} s^{(k)} + \Omega \alpha^{(k)} \| s^{(k)} \|^{2}$$

Thus by using (3.1.4) we obtain:

$$\alpha^{(k)} \geq -\frac{1-\sigma}{\Omega} \frac{g^{(k)} s^{(k)}}{\|s^{(k)}\|^2}$$

which can be substituted into (3.1.5), and by using (3.1.6) and (4.2.26) it follows that:

$$f(x^{(k+1)}) \leq f(x^{(k)}) - c_3 \|g^{(k)}\|^2 \cos^2(\theta^{(k)})$$
,

where $c_3 = \rho(1-\sigma)/\Omega > 0$. Thus since f(x) is bounded in the level set (3.1.10), $\sum_k \|g^{(k)}\|^2 \cos^2(\theta^{(k)})$ is convergent. And because

 $\|g^{(k)}\|$ is bounded below, this contradicts (4.2.27). Since this contradiction arises from (4.2.23), it follows that (4.2.23) is false and therefore (3.2.3) is true.

2.3 Computational Performance of Hybrid 1.

This globally convergent hybrid algorithm was tested on several test problems, namely the extended Rosenbrock, Wood, Miele & Cantrell, Powell, Dixon, Beale and Engwall's test problems, each of which were considered with 26 different numbers of variables resulting in a total of 182 cases. These test problems are described in the final Chapter entitled "Discussion and Conclusions". The program used for testing the method is the N.A.G. routine EØ4DBF, in which the computation of the update $\beta^{(k)}$ was modified to compute $\beta^{(k)}$ as defined in (4.2.4). The results obtained by Hybrid 1 on each individual case are given in Appendix 2. Tables (2.6.i) for i = 1, 2, ..., 7 whereas the overall results with the comparison of the figures obtained by Hybrid 1 against those obtained by both the Fletcher-Reeves and Polak-Ribière methods are given in Appendix 3, Table (3.6). The individual results reported in Appendix 2 show that in many cases Hybrid 1 was a significant improvement on both straight-forward Fletcher-Reeves and Polak-Ribière algorithms, for instance on the 40, 180, 200, 480, 500 variable Wood test problems, the 4, 100, 280 variable Miele & Cantrell test functions, the 4, 20, 260, 340, 420, 480 variable Powell test functions and 40, 80, 120, 140, 200, 320, 440, 480 and 500 variable Dixon test functions. There have also been cases however, where both the Fletcher-Reeves and the Polak-

Ribière algorithms performed much better than Hybrid 1. For instance on the 60, 160, 260, 360, 460 variable Rosenbrock test functions and the 180, 220, 240, 260, 280, 300, 320 variable Beale test functions. As we can see in Table (2.6.1) of Appendix 2, this inefficiency occurred especially when Hybrid 1 was tested on the extended Rosenbrock and Beale test problems.

In the following remark, we attempt to explain some of the reasons for this inefficiency and we also explain how the features that cause it, are likely to occur when Hybrid 1 is tested on problems such as the two-variable Rosenbrock test function.

Remark 2:

Suppose that at the kth iteration we face the situation sketched in Figure 4.2.1 below. Explicitly, we have $\beta^{(k-1)}(F.R)$ and $\beta^{(k-1)}(P.R)$ both positive and $\beta^{(k-1)}(P.R)$ is greater than $\beta^{(k-1)}(F.R)$. In this case (4.2.3) is obviously not satisfied and therefore by definition of $\beta^{(k-1)}$ in (4.2.4), Hybrid 1 will choose to use $\beta^{(k-1)}(F.R)$ instead of $\beta^{(k-1)}(P.R)$. However, as can be seen in Figure 4.2.1, searching along s^(k)(P.R) obtained by using $\beta^{(k-1)}(P.R)$ would lead to a better approximation $x^{(k+1)}$ than the approximation expected to be obtained by Hybrid 1 which searches along s^(k)(F.R) obtained by using $\beta^{(k-1)}(F.R)$. Therefore, Hybrid 1 could prove to be quite inefficient if this situation occurs frequently.

Figure 4.2.2 shows the contours of the two-variable Rosenbrock test function. We can see that when the solution path is descending the valley away from the origin (0, 0) towards the optimal solution

Figure 4.2.1 : A situation where the Polak-Ribière direction of search leads to a better approximation to the minimum than the Fletcher-Reeves direction of search. Because $\beta^{(k-1)}(F.R)$ is less than $\beta^{(k-1)}(P.R)$, by definition (4.2.4) Hybrid 1 chooses to use the Fletcher-Reeves direction. This shows a possible inefficiency of Hybrid 1 and indicates how to improve it, as will be seen in Section 3 below.

Figure 4.2.2 : Contours of the 2-variable Rosenbrock's test function. The situation shown in Figure 4.2.1 is very likely to occur as shown here.

(1, 1), the situation shown in Figure 4.2.1 is most likely to occur on every iteration thereafter whenever $\beta(P.R) > \beta(F.R)$. This is perhaps the reason for which Hybrid 1 performed quite poorly on the extended Rosenbrock's test problems.

3. AN IMPROVED HYBRID ALGORITHM: HYBRID 2.

To improve the situation described above, one could think of allowing certain values of $\beta(P.R)$, that do not satisfy (4.2.3), to be used as long as the angle between the negative gradient $-g^{(k)}$ and the current search direction $s^{(k)}$ is not too close to $\frac{\pi}{2}$.

Shanno (1985) gives an angle test to determine when conjugate gradient algorithms should be restarted with a steepest descent direction. His procedure is of interest to what will follow and is therefore briefly described below.

His argument is based on the fact that if a series $\sum_k t(k)$ is divergent then for any $\tau > 0$, the series $\tau \sum_k t(k)$ is also divergent. Using the fact that the Fletcher-Reeves algorithm is globally convergent when exact line searches are performed we have:

$$\sum_{k} \cos^{2}(\theta^{(k)}) = \sum_{k} \frac{1}{\|g^{(k)}\|^{2} \sum_{\ell=1}^{k} \|g^{(\ell)}\|^{-2}}$$
(4.3.1)

is a divergent series. It is immediately obvious that if $\sum_k \cos^2(\theta^{(k)})$ is divergent, then for any $\tau > 0$, $\tau \sum_k \cos^2(\theta^{(k)})$ is divergent. Thus for any $\tau > 0$, we define $\gamma^{(k)}$ by:

$$\gamma^{(k)^{2}} = \frac{\tau}{\|g^{(k)}\|^{2} \sum_{\substack{k=1 \\ k=1}}^{k} \|g^{(k)}\|^{-2}}$$
(4.3.2)

Shanno's proposed algorithm is then to calculate a trial direction $\hat{s}^{(k)}$ by any desired conjugate gradient formula, then calculate

$$\cos^{2}(\hat{\theta}^{(k)}) = \left(g^{(k)^{T}} \hat{s}^{(k)}\right)^{2} / \left(\|g^{(k)}\|^{2} \cdot \|\hat{s}^{(k)}\|^{2}\right) \qquad (4.3.3)$$

The final search vector s^(k) is chosen by:

$$s^{(k)} = \begin{cases} \hat{s}^{(k)} & \text{if } \cos^{2}(\hat{\theta}^{(k)}) \ge \gamma^{(k)^{2}} \\ & & \\ -g^{(k)} & \text{if } \cos^{2}(\hat{\theta}^{(k)}) < \gamma^{(k)^{2}} \end{cases}$$
(4.3.4)

This test ensures that the angle between $-g^{(k)}$ and $s^{(k)}$ is small enough to be bounded away from $\frac{\pi}{2}$.

A possible hybrid algorithm would be to use this test for every $\beta(P.R)$ that is greater than $\beta(F.R)$. $\beta(P.R)$ is then used if $\cos^2(\theta^{(k)}) \ge \gamma^{(k)^2}$ and $\beta(F.R)$ is used instead otherwise. In other words one could use the following algorithm to compute $\beta^{(k-1)}$ in (3.1.7) at each iteration k.

- Step 1: if $\beta^{(k-1)}(P.R) < 0$ then $\beta^{(k-1)} = \beta^{(k-1)}(F.R)$, return. Otherwise go to step 2.
- Step 2: if (4.2.3) holds then $\beta^{(k-1)} = \beta^{(k-1)}$ (P.R), return. Otherwise go to step 3.
- <u>Step 3</u>: if $\cos^2(\theta^{(k)}(P.R)) \ge \gamma^{(k)^2}$ then $\beta^{(k-1)} = \beta^{(k-1)}(P.R)$, return. Otherwise $\beta^{(k-1)} = \beta^{(k-1)}(F.R)$, return.

(4.3.5)

This hybrid algorithm (Angle Test Hybrid) was tested on the same test functions used to test Hybrid 1 and showed a considerable improvement on Fletcher-Reeves, Polak-Ribiere and Hybrid 1 algorithms. Three different values of τ were tried, namely τ = 0.1, τ = 0.01 and τ = 0.001 and the second value provided better results especially for high dimensional cases. The great improvement of the Angle Test Hybrid over Hybrid 1 on the Rosenbrock test problem confirms the fact that the situation described in Remark 2 did cause some inefficiency of Hybrid 1 and that this test does indeed help to avoid it. The individual results for this hybrid algorithm are given in Tables (2.i.j) for i = 8.9 and 10 and $j = 1, 2, 3, \dots, 7$ Appendix 2, whereas the overall results together with the comparison of the figures obtained by the Angle Test Hybrids for different values of τ against those obtained by the straight-forward Fletcher-Reeves and Polak-Ribière methods are given in Appendix 3, Tables (3.8), (3.9) and (3.10).

When exact line searches are performed at each iteration, the hybrid algorithm using (4.3.5) to compute the update β , is shown in subsection 3.2.1 below to have a descent property and to be globally convergent. However, when inexact line searches are used throughout the algorithm, the angle test used in Step 3 of (4.3.5) does not seem to ensure a descent property to hold with which it would be possible to prove global convergence. As it will become clear in the proof of the descent property in subsection 3.2.2 to follow, we find that by imposing the additional condition in Step 3 of (4.3.5) that:

$$\beta^{(k-1)}(P.R) < \frac{1}{2\sigma} \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2}$$
(4.3.6)

we ensure a descent property to hold and hence the limit (3.2.3) is achieved, where σ is the factor in the line search. Condition (4.3.6) is not needed when exact line searches are used for the simple reason that it is always satisfied. (When exact line searches are used then $\sigma = 0$ and (4.3.6) becomes $\beta^{(k-1)}(P.R) < +\infty$ which is true since $g^{(k)}$ is bounded above in the level set (3.1.10)).

3.1 Definition of the New Hybrid Algorithm: Hybrid 2.

We suggest the use of a new Hybrid Conjugate Gradient Method (Hybrid 2) where the update $\beta^{(k-1)}$ at each iteration k is computed by the following algorithm:

Step 1: if
$$\beta^{(k-1)}(P.R) < 0$$
 then $\beta^{(k-1)} = \beta^{(k-1)}(F.R)$, return.
If not go to step 2.

- Step 2: if (4.2.3) is true then $\beta^{(k-1)} = \beta^{(k-1)}(P.R)$, return. If not go to step 3.
- <u>Step 3</u>: if $\cos^{2}(\theta^{(k)}(P,R)) \ge \gamma^{(k)^{2}}$ and $\beta^{(k-1)}(P,R) < \frac{1}{2\sigma} \frac{\|g^{(k)}\|^{2}}{\|g^{(k-1)}\|^{2}}$ then $\beta^{(k-1)} = \beta^{(k-1)}(P,R)$, return. Otherwise $\beta^{(k-1)} = \beta^{(k-1)}(F,R)$, return. (4.3.7)

This conjugate gradient method Hybrid 2, using algorithm (4.3.7) to compute $\beta^{(k-1)}$ in (3.1.7) produces a sequence of updates $\{\beta^{(\ell)}, \ell = 1, 2, ...\}$ whose elements $\beta^{(\ell)}$ fall into two categories: Category 1:

$$0 \leq \beta^{(\ell)} \leq \beta^{(\ell)}(F.R) = \frac{\|g^{(\ell+1)}\|^2}{\|g^{(\ell)}\|^2} , \qquad (4.3.8)$$

Category 2:

$$\beta^{(\ell)} > \beta^{(\ell)}(F.R) = \frac{\|g^{(\ell+1)}\|^2}{\|g^{(\ell)}\|^2},$$
 (4.3.9)

with

$$\cos^2 \theta^{(\ell+1)} \ge \gamma^{(\ell+1)^2}$$
 (4.3.10)

and (4.3.6) holds when inexact line searches are used.

This hybrid algorithm Hybrid 2 needs the storage of an extra vector compared with straight-forward Fletcher-Reeves or Polak-Ribière algorithms. This is to store the trial direction of search vector to compute $\cos^2(\theta^{(k)})$ in Step 3 of (4.3.7). As for computer time used for the extra operations we only need to compute $\cos^2(\theta^{(k)})$ and $\gamma^{(k)}^2$ at iterations where a beta from category 2 needs to be tested for use.

Conditions (4.3.6) and (4.3.10) seem intuitively to say the same thing and should therefore be equivalent but it has not been possible to prove this. Satisfying condition (4.3.10) is saying that the angle $\theta^{(k)}$ between the negative gradient $-g^{(k)}$ and the current search direction $s^{(k)}$ is bounded away from orthogonality, i.e.,

$$\cos^{2}(\theta^{(k)}) \ge \gamma^{(k)^{2}} \Rightarrow \theta^{(k)} \le r^{(k)}$$

where $r^{(k)}$ is some angle such that $r^{(k)} < \frac{\pi}{2}$. Then:

$$\theta^{(k)} \leq r^{(k)} \Rightarrow \beta^{(k-1)} s^{(k-1)} \leq B(k)$$

 $\Rightarrow \beta^{(k-1)} \leq C(k)$

where B(k) and C(k) are quantities depending on $g^{(k)}$ and hence on k. It would be useful to prove the equivalence of these two conditions for some suitable values of σ and τ or at least to prove that (4.3.6) implies (4.3.10) because then one can use only condition (4.3.6) with no extra storage or extra computation. An algorithm using (4.3.7) with only condition (4.3.6) in Step 3 was used on the same test functions. The results for this hybrid algorithm (Beta Test Hybrid) are discussed in the final Chapter "Discussion and Conclusions" and are given in Appendices 2 and 3, Tables (2.11.i) i = 1,2,3...,7 and Table(3.11).

3.2 Descent Property and Global Convergence of Hybrid 2.

3.2.1 Exact Line Searches.

(a) Descent property:

This follows from the fact that a descent property holds on all iterations for both Fletcher-Reeves and Polak-Ribière methods when the line search is exact, which has already been shown (3.2.2).

(b) Global convergence:

Since exact line searches are performed condition (4.3.6) is always satisfied and need not be used. Therefore algorithm (4.3.5) to compute the update β at each iteration is used instead of algorithm (4.3.7).

Referring to Theorem 4.2.1, where it was shown that Hybrid 1 was globally convergent when exact line searches are performed, all we need, to show that Hybrid 2 is globally convergent when exact line searches are performed, is to establish a similar inequality to (4.2.12). The following theorem gives this inequality.

Theorem 4.3.1:

If an exact line search is performed at each iteration and if $\beta^{(k)}$ is computed from algorithm (4.3.5) at each iteration and if τ is such that $0 < \tau \leq 1$, then the inequality:

$$\| \mathbf{s}^{(k)} \|^{2} \leq \frac{1}{\tau} \sum_{\ell=1}^{k} \| \mathbf{g}^{(k)} \|^{4} / \| \mathbf{g}^{(\ell)} \|^{2}$$
(4.3.11)

holds for all k.

Proof:

We prove this theorem by induction.

For k = 1 we have:

$$\| s^{(1)} \|^{2} = \| g^{(1)} \|^{2} \leq \frac{1}{\tau} \| g^{(1)} \|^{2} = \frac{1}{\tau} \sum_{\ell=1}^{1} \| g^{(1)} \|^{4} / \| g^{(\ell)} \|^{2}$$

Now suppose that at iteration (k-1) we have:

$$\| s^{(k-1)} \|^2 \leq \frac{1}{\tau} \sum_{\ell=1}^{k} \| g^{(k-1)} \|^4 / \| g^{(\ell)} \|^2$$

At iteration k, Hybrid 2 could either use a beta from category 1 or a beta from category 2.

If $\beta^{(k-1)}$ is calculated from category 1, then

$$\beta^{(k-1)} \leq \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2}$$
.

Therefore:

$$\| s^{(k)} \|^2 = \| g^{(k)} \|^2 + \beta^{(k-1)} \| s^{(k-1)} \|^2$$

$$\leq \| g^{(k)} \|^{2} + \frac{\| g^{(k)} \|^{4}}{\| g^{(k-1)} \|^{4}} \left[\frac{1}{\tau} \| g^{(k-1)} \|^{4} \sum_{\ell=1}^{k-1} \| g^{(\ell)} \|^{2} \right]$$

Because $0 < \tau \leq 1$ we then have:

$$\| s^{(k)} \|^{2} \leq \frac{\| g^{(k)} \|^{2}}{\tau} + \frac{1}{\tau} \| g^{(k)} \|^{4} \sum_{\ell=1}^{k-1} \| g^{(\ell)} \|^{-2}$$
$$= \frac{1}{\tau} \| g^{(k)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2} .$$

If $\beta^{(k-1)}$ is calculated from category 2, then by definition of Hybrid 2 we have:

$$\cos^{2}(\theta^{(k)}) = \frac{\|g^{(k)}\|^{2}}{\|s^{(k)}\|^{2}} \ge \frac{\tau}{\|g^{(k)}\|^{2}} \sum_{\ell=1}^{\tau} \|g^{(\ell)}\|^{-2}$$
$$\Rightarrow \|s^{(k)}\|^{2} < \frac{1}{\tau} \|g^{(k)}\|^{4} \sum_{\ell=1}^{k} \|g^{(\ell)}\|^{-2}$$

Therefore no matter what beta is used at any stage of the algorithm Hybrid 2, inequality (4.3.11) holds for every k. The global convergence proof follows in the same manner as that following inequality (4.2.11).

_2

3.2.2 Inexact Line Searches.

(a) Descent property:

When inexact line searches are performed with Hybrid 2, algorithm (4.3.7) is used to compute beta. So, every time a beta is chosen from category 2, we have:

$$\beta^{(k-1)} = \frac{\|g^{(k)}\|^2 - g^{(k)^T}g^{(k-1)}}{\|g^{(k-1)}\|^2} < \frac{1}{2\sigma} \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2}$$
$$\Rightarrow -\frac{g^{(k)^T}g^{(k-1)}}{\|g^{(k)}\|^2} < \frac{1 - 2\sigma}{2\sigma}$$
(4.3.12)

and we also have:

$$\beta^{(k-1)} > \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2} \Rightarrow -\frac{g^{(k)}g^{(k-1)}}{\|g^{(k)}\|^2} > 0$$

Therefore we have the relation:

$$0 < -\frac{g^{(k)} g^{(k-1)}}{\|g^{(k)}\|^2} < \frac{1-2\sigma}{2\sigma} .$$
 (4.3.13)

Theorem 4.3.2:

The descent property (3.1.6) holds at every iteration of Hybrid 2 when an inexact line search satisfying (3.1.4) with $\sigma < \frac{1}{2}$ is performed.

Proof:

The method of proof is to show by induction that the inequalities:

$$-1 - 2\sigma - c(k) \leq \frac{g^{(k)} s^{(k)}}{\|g^{(k)}\|^{2}} \leq -1 + 2\sigma + c(k) \qquad (4.3.14)$$

hold for all k such that $g^{(k)} \neq 0$, where

$$0 \leq c(k) < 1 - 2\sigma$$

It will then follow inductively that the descent property (3.1.6) holds.

For k = 1 we have

$$-1 - 2\sigma - c(k) \leq -1 \leq -1 + 2\sigma + c(k)$$

holds for any value of c(k) such that $0 \leq c(k) < 1 - 2\sigma$. This shows that (4.3.14) is satisfied for k = 1. Now assume that (4.3.14) is true for any $k \geq 1$. Since $0 \leq c(k) < 1 - 2\sigma$, it is clear that the right hand side of (4.3.14) is negative for any $\sigma < \frac{1}{2}$ and hence the descent property (3.1.6) is satisfied on iteration k. From the definition of $s^{(k+1)}$ (3.1.7) it follows that:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} = -1 + \beta^{(k)} \frac{g^{(k+1)^{T}} s^{(k)}}{\|g^{(k+1)}\|^{2}} . \qquad (4.3.15)$$

 $\beta^{(k)}$ could either be computed from Category 1 or from Category 2. We shall consider each case separately showing that for both cases (4.3.14) holds.

$$\beta^{(k)}$$
 from Category 1:
If $\beta^{(k)}$ is computed from Category 1, then we have:

$$0 \leq \beta^{(k)} \leq \frac{\|g^{(k+1)}\|^2}{\|g^{(k)}\|^2} .$$
 (4.3.16)

Using (3.1.4) we get:

$$\frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 - \sigma \beta^{(k)} \frac{g^{(k)} s^{(k)}}{\|g^{(k+1)}\|^{2}}.$$
(4.3.17)

Then substituting (4.3.16) into (4.3.17) and using the induction assumption that $g^{(k)}{}^{T} s^{(k)} < 0$, we get:

$$\frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^2} \leq -1 - \sigma \frac{g^{(k)} s^{(k)}}{\|g^{(k)}\|^2} .$$
(4.3.18)

Using the induction assumption again that

$$\frac{g^{(k)}}{g^{(k)}} \frac{g^{(k)}}{s^{(k)}} \ge -1 - 2\sigma - c(k)$$

with

$$0 \leq c(k) < 1 - 2\sigma$$

we get

$$\frac{g^{(k)}}{g^{(k)}} \frac{s^{(k)}}{2} \ge -2.$$
 (4.3.19)

Substituting (4.3.19) into (4.3.18), we get:

$$\frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^2} \leq -1 + 2\sigma .$$

Therefore for any c(k+1) such that $0 \leq c(k+1) < 1 - 2\sigma$ we have

$$\frac{g^{(k+1)}}{\|g^{(k+1)}\|^2} \leq -1 + 2\sigma + c(k+1) . \qquad (4.3.20)$$

On the other hand, substituting (3.1.4) into (4.3.15) also gives

$$\frac{g^{(k+1)^{T}}s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \ge -1 + \sigma\beta^{(k)}\frac{g^{(k)^{T}}s^{(k)}}{\|g^{(k+1)}\|^{2}} .$$
(4.3.21)

Then substituting (4.3.16) into (4.3.21) and using the induction assumption that $g^{(k)}{}^{T} s^{(k)} < 0$, we get:

÷

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \ge -1 + \sigma \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} .$$
(4.3.22)

Using the induction assumption again that

$$\frac{g^{(k)}}{\|g^{(k)}\|^2} \ge -2 \qquad (see (4.3.19))$$

and substituting (4.3.19) into (4.3.22), we get:

$$\frac{g^{(k+1)}}{\|g^{(k+1)}\|^2} \ge -1 - 2\sigma .$$

Therefore for any c(k+1) such that $0 \leq c(k+1) < 1 - 2\sigma$, we have:

$$\frac{g^{(k+1)}}{\|g^{(k+1)}\|^2} \ge -1 - 2\sigma - c(k+1) . \qquad (4.3.23)$$

Finally combining (4.3.20) and (4.3.23) we have:

$$-1 - 2\sigma - c(k+1) \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 + 2\sigma + c(k+1)$$
(4.3.24)

with $0 \leq c(k+1) < 1 - 2\sigma$

which is (4.3.14) where k is replaced by k+1.

 $\beta^{(k)}$ from Category 2:

If $\beta^{(k)}$ is computed from Category 2, then (4.3.13) holds. So substituting (3.1.4) into (4.3.15) we have:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 - \sigma \beta^{(k)} \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k+1)}\|^{2}}.$$
(4.3.25)

Since $\beta^{(k)}$ is from Category 2 then

$$\beta^{(k)} = \frac{\|\frac{g^{(k+1)}\|^2 - g^{(k+1)^T}g^{(k)}}{\|g^{(k)}\|^2}$$

By substituting this into (4.3.25), we get:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 - \sigma \left[\frac{\|g^{(k+1)}\|^{2} - g^{(k+1)^{T}} g^{(k)}\|}{\|g^{(k)}\|^{2}} \right] \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k+1)}\|^{2}}$$
$$= -1 - \sigma \left[1 - \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k+1)}\|^{2}} \right] \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)$$

Then using (4.3.19) and the left-hand side of (4.3.13), we get:

$$\frac{g^{(k+1)} g^{(k+1)}}{\|g^{(k+1)}\|^2} \leqslant -1 + 2\sigma - 2\sigma \frac{g^{(k+1)} g^{(k)}}{\|g^{(k+1)}\|^2} . \qquad (4.3.26)$$

But we have from (4.3.12) that:

$$-\frac{g^{(k+1)}}{\|g^{(k+1)}\|^{2}} < \frac{1-2\sigma}{2\sigma} \Rightarrow -2\sigma \frac{g^{(k+1)}}{\|g^{(k+1)}\|^{2}} < 1-2\sigma$$

we then let

$$c(k+1) = -2\sigma \frac{g^{(k+1)}}{\|g^{(k+1)}\|^2}$$

and we have:

$$\frac{g^{(k+1)}}{\|g^{(k+1)}\|^2} \leq -1 + 2\sigma + c(k+1)$$
(4.3.27)

with $0 \le c(k+1) \le 1 - 2\sigma$. On the other hand, by substituting (3.1.4) into (4.3.15) we also get:

$$\frac{g^{(k+1)^{T}}s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \ge -1 + \sigma\beta^{(k)}\frac{g^{(k)^{T}}s^{(k)}}{\|g^{(k+1)}\|^{2}} \qquad (4.3.28)$$

Then by substituting $\beta^{(k)} = \beta(P.R)$ into (4.3.28) we get:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \ge -1 + \sigma \left[\frac{\|g^{(k+1)}\|^{2} - g^{(k+1)^{T}} g^{(k)}}{\|g^{(k)}\|^{2}} \right] \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k+1)}\|^{2}}$$
$$= -1 + \sigma \left[1 - \frac{g^{(k+1)^{T}} g^{(k)}}{\|g^{(k+1)}\|^{2}} \right] \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} + \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} + \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} + \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} + \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} + \frac{g^{(k)^{T}} s^{(k)}}{\|g^{(k)}\|^{2}} \cdot \frac{g^{(k)^{T}} s^{(k)}}{$$

Then using (4.3.19) and the left-hand side of (4.3.13) again we get:

$$\frac{g^{(k+1)} f_{g^{(k+1)}}}{\|g^{(k+1)}\|^{2}} \ge -1 - 2\sigma + 2\sigma \frac{g^{(k+1)} f_{g^{(k+1)}}}{\|g^{(k+1)}\|^{2}}$$

And again if we let

$$c(k+1) = -2\sigma \frac{g^{(k+1)^{T}}g^{(k)}}{\|g^{(k+1)}\|^{2}}$$

we get:

$$\frac{g^{(k+1)}}{\|g^{(k+1)}\|^2} \ge -1 - 2\sigma - c(k+1)$$
(4.3.29)
with $0 \leq c(k+1) < 1 - 2\sigma$.

Combining (4.3.27) and (4.3.29) we get:

$$-1 - 2\sigma - c(k+1) \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 + 2\sigma + c(k+1)$$
(4.3.30)

with $0 \leq c(k+1) < 1 - 2\sigma$ which is (4.3.14) with k replaced by k+1.

Therefore no matter what category beta is calculated from we have:

$$-1 - 2\sigma - c(k+1) \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 + 2\sigma + c(k+1)$$

with

$$c(k+1) < 1 - 2\sigma$$
.

The induction is thus completed showing that the descent property (3.1.6) holds on every iteration of Hybrid 2 when inexact line searches are performed.

(b) Global convergence:

0 \$

We now proceed to show that Hybrid 2, using algorithm (4.3.7) to compute the update $\beta^{(k-1)}$ at each iteration k, is globally convergent when an inexact line search satisfying (3.1.4) with $\sigma < \frac{1}{2}$ is performed at each iteration. This is done by showing that:

$$\sum_{k} \cos^{2}(\theta^{(k)}) = + \infty$$
(4.3.31)

holds. Before proving that (4.3.31) holds we need to establish an inequality similar to (4.2.22) for $||s|^{(k)}||_{,k}^{2} = 1,2,...$ The following Lemma gives this inequality.

Lemma 4.3.1:

If an inexact line search satisfying (3.1.4) with $\sigma < \frac{1}{2}$ is performed at each iteration k, if $\beta^{(k-1)}$ is computed from algorithm (4.3.7) at each iteration k and if τ in $\gamma^{(k)^2}$ is such that $0 < \tau \le 1$, then the inequality:

$$\| s^{(k)} \|^{2} < \frac{4}{\tau} \| g^{(k)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2}$$
(4.3.32)

holds at each iteration k.

Proof:

We prove this Lemma by induction. For k = 1 inequality (4.3.32) is obviously true. We now assume that it holds for any $k \ge 1$ and we shall show that it then holds for k+1.

On iteration k+1, $\beta^{(k)}$ could either be computed from Category 1 of from Category 2. We shall show that in both cases (4.3.32) holds when k is replaced by k+1.

$\beta^{(k)}$ from Category 1:

From the definition of $s^{(k+1)}$ in (3.1.7) we have:

$$\| \mathbf{s}^{(k+1)} \|^2 = \| \mathbf{g}^{(k+1)} \|^2 - 2\beta^{(k)} \mathbf{g}^{(k+1)^{\mathrm{T}}} \mathbf{s}^{(k)} + \beta^{(k)^2} \| \mathbf{s}^{(k)} \|^2$$

Using (3.1.4) we obtain:

$$\| \mathbf{s}^{(k+1)} \|^2 \leq \| \mathbf{g}^{(k+1)} \|^2 - 2\sigma\beta^{(k)} \mathbf{g}^{(k)} \mathbf{s}^{(k)} + \beta^{(k)} \| \mathbf{s}^{(k)} \|^2$$

Then using (4.3.19), (4.3.8) and the induction assumption (4.3.32) we get:

$$\| s^{(k+1)} \|^{2} \leq \| g^{(k+1)} \|^{2} + 4\sigma \| g^{(k+1)} \|^{2} + \frac{4}{\tau} \| g^{(k+1)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2}$$
$$= \| g^{(k+1)} \|^{4} \left[(1 + 4\sigma) \frac{1}{\| g^{(k+1)} \|^{2}} + \frac{4}{\tau} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2} \right].$$

Because $\sigma < \frac{1}{2}$ then 1 + 4 $\sigma < 3$ and because $0 < \tau \le 1$ then $\frac{4}{\tau} \ge 4$. Therefore $\frac{4}{\tau} > 1 + 4\sigma$ and so we have:

$$\| \mathbf{s}^{(k+1)} \|^2 < \frac{4}{\tau} \| \mathbf{g}^{(k+1)} \|^4 \sum_{\ell=1}^{k+1} \| \mathbf{g}^{(\ell)} \|^{-2}$$

which is (4.3.32) with k replaced by k+1.

$$\frac{\beta^{(k)} \text{ from Category 2:}}{\text{Since } \beta^{(k)} \text{ is from Category 2 then (4.3.10) holds. We then}}$$

have:

$$\cos^{2}(\theta^{(k+1)}) \geq \frac{\tau}{\|g^{(k+1)}\|^{2} \sum_{\ell=1}^{k+1} \|g^{(\ell)}\|^{-2}}$$

$$\cos^{2}(\theta^{k+1}) = \frac{\left[g^{(k+1)^{T}} s^{(k+1)}\right]^{2}}{\|g^{(k+1)}\|^{2} \cdot \|s^{(k+1)}\|^{2}}$$

But

Therefore we have:

$$\frac{\left(g^{(k+1)} s^{(k+1)}\right)^{2}}{\left|g^{(k+1)}\right|^{2} \cdot \left\|s^{(k+1)}\right\|^{2}} \ge \frac{\tau}{\left\|g^{(k+1)}\right\|^{2} \sum_{\ell=1}^{k+1} \left\|g^{(\ell)}\right\|^{-2}} \quad (4.3.33)$$

Using Theorem 4.3.2, we have:

$$\frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \ge -1 - 2\sigma - c(k+1) \ge -2$$

$$\Rightarrow 0 \ge g^{(k+1)^{T}} s^{(k+1)} \ge -2 \|g^{(k+1)}\|^{2}$$

$$\Rightarrow (g^{(k+1)^{T}} s^{(k+1)})^{2} \le 4 \|g^{(k+1)}\|^{4} . \qquad (4.3.34)$$

Substituting (4.3.34) into (4.3.33) we obtain:

$$\frac{4 \|g^{(k+1)}\|^2}{\|s^{(k+1)}\|^2} \ge \frac{\tau}{\|g^{(k+1)}\|^2 \sum_{\substack{\ell=1 \\ l = 1}}^{\tau} \|g^{(\ell)}\|^{-2}}$$

f rom which we finally obtain:

$$\| \mathbf{s}^{(k+1)} \|^2 \leq \frac{4}{\tau} \| \mathbf{g}^{(k+1)} \|^4 \sum_{\ell=1}^{k+1} \| \mathbf{g}^{(\ell)} \|^{-2}$$

which is (4.3.32) with k replaced by k+1. So no matter what category the update $\beta^{(k)}$ is computed from, inequality (4.3.32) holds for all iterations of Hybrid 2.

A consequence of this Lemma is the following global convergence result.

Theorem 4.3.3:

If the set (3.1.10) is bounded, if f(x) is twice continuously differentiable, and if $\alpha^{(k)}$ is any value satisfying (3.1.4) and (3.1.5) with $\rho < \sigma < \frac{1}{2}$, then equation (3.2.3) holds for Hybrid 2.

Proof:

We prove this theorem by contradiction. Suppose that (3.2.3) is not true, then there exists a positive constant, ε say, such that:

$$\|g^{(k)}\| \ge \varepsilon > 0$$
 for all k . (4.3.35)

But $g^{(k)}$ is bounded above in the level set (3.1.10). Hence from (4.3.32) in Lemma 4.3.1, we have:

$$\|s^{(k)}\|^2 \leq c_1 k$$
 (4.3.36)

where c₁ is a positive constant.

. .

using the descent property of Theorem 4.3.2 we have:

$$\frac{g^{(k)}}{g^{(k)}} \frac{g^{(k)}}{2} \leq -1 + 2\sigma + c(k) . \qquad (4.3.37)$$

But we know that for all k we have $0 < c(k) < 1 - 2\sigma$. Therefore there exists a positive constant μ such that:

 $0 < c(k) \le \mu < 1 - 2\sigma$. (4.3.38)

It then follows that (4.3.37) still holds when c(k) is replaced by μ , i.e.

$$\frac{g^{(k)^{T}} g^{(k)}}{\|g^{(k)}\|^{2}} \leq -1 + 2\sigma + \mu < 0$$
(4.3.39)

$$\Rightarrow \cos^{2}(\theta^{(k)}) \ge (-1 + 2\sigma + \mu)^{2} \frac{\|g^{(k)}\|^{2}}{\|s^{(k)}\|^{2}} \qquad (4.3.40)$$

Therefore if $\beta^{(k)}$ is computed from either category we have

$$\cos^{2}(\theta^{(k)}) \ge c_{2} \frac{\|g^{(k)}\|^{2}}{\|s^{(k)}\|^{2}}$$
 (4.3.41)

$$C_{2} = (-1 + 2\sigma + \mu)^{2} > 0$$

From (4.3.36) and (4.3.41) it follows that:

$$\cos^{2}(\theta^{(k)}) \ge c_{2} \sum_{k} \|g^{(k)}\|^{2} / \|s^{(k)}\|^{2}$$
$$\ge c_{3} \sum_{k} k^{-1}$$
(4.3.42)

where c_3 is a positive constant. Hence the series $\sum_k \cos^2(\theta^{(k)})$ diverges. However it is possible to contradict this result using the line search conditions. If Ω is an upper bound on $\|\nabla^2 f(x)\|$, where x is any point in the level set (3.1.10), then we have:

$$g^{(k+1)^{T}} s^{(k)} \leq g^{(k)^{T}} s^{(k)} + \Omega \alpha^{(k)} \| s^{(k)} \|^{2}$$

Thus by using (3.1.4) we obtain:

$$\alpha^{(k)} \geq -\frac{1-\sigma}{\Omega} \frac{g^{(k)} s^{(k)}}{\|s^{(k)}\|^2}$$

which can be substituted in (3.1.5), and by using (3.1.6) and the definition of $\cos^2(\theta^{(k)})$, it follows that:

$$f(x^{(k+1)}) \leq f(x^{(k)}) - c_4 \|g^{(k)}\|^2 \cos^2(\theta^{(k)})$$

where

$$c_{\lambda} = \rho(1-\sigma)/\Omega > 0.$$

Thus since f(x) is bounded, $\sum_{k} \|g^{(k)}\|^2 \cos^2(\theta^{(k)})$ is convergent and because $\|g^{(k)}\|$ is also bounded below this contradicts (4.3.42). Since this contradiction arises from (4.3.35), it follows that (4.3.35) is false and therefore (3.2.3) is true, and the global convergence of Hybrid 2 is established.

3.3 Computational Performance of Hybrid 2.

Here also, the N.A.G. routine EØ4DBF, in which the computation of the update $\beta^{(k)}$ was modified to compute $\beta^{(k)}$ as defined in (4.3.7), was used to test Hybrid 2 on the same test problems on which Hybrid 1 and all the other algorithms studied herein were tested. Three different values of τ , namely $\tau = 10^{-4}$, $\tau = 10^{-6}$ and $\tau = 10^{-8}$, were tried in an attempt to find the best possible value for this scalar. The choice of these three values came from the fact that it was noted that the computational efficiency of the method deteriorated as τ got larger than 10^{-4} . The results obtained for each individual case and for each value of τ are given in Appendix 2, Tables (2.i.j) for i = 12, 13 and 14 and j = 1,2,3,...,7, whereas the overall results together with the figures obtained by Hybrid 2 for each of the three values of τ mentioned above compared against the figures obtained by both

the Fletcher-Reeves and the Polak-Ribiere methods are given in Appendix 3, Tables (3.12), (3.13) and (3.14). It can be seen from these tables that in terms of smallest total for the index of computational labour (denoted NC), Hybrid 2 seems to provide better results as τ decreases although the difference between $\tau = 10^{-4}$ and $\tau = 10^{-6}$ was very small. The value $\tau = 10^{-8}$ however, provides the best results compared to all the methods described so far herein. The percentages of improvement achieved by Hybrid 2 with $\tau = 10^{-8}$ over the methods of Fletcher-Reeves and Polak-Ribière were as follows:

48% improvement in terms of NC and 38% improvement in terms of CPU time needed to solve all problems considered over the method of Fletcher-Reeves and,

8% improvement in terms of NC and 7% improvement in terms of CPU time needed to solve all problems considered, over the method of Polak-Ribière.

A more detailed discussion of the results obtained by the three values of τ is given in the final Chapter "Discussion and Conclusions".

Chapter 5

More Efficient Hybrid Conjugate Gradient Techniques

1. INTRODUCTION.

Whereas Hybrid 1 had the drawback of being too restrictive in choosing to use the Polak-Ribière update according to its switching criterion from one update to the other, which resulted in an eventual computational inefficiency of the algorithm, Hybrid 2 on the other hand, suffers the drawback of the need to store an extra n-dimensional vector for the trial direction of search $\hat{s}^{(k)}$ at each iteration and the need for some extra computations that resulted in slightly higher CPU time at each iteration. The purpose of this chapter is to try to overcome these difficulties encountered with these two hybrid algorithms, in an attempt to produce an even more efficient hybrid conjugate gradient method that not only out-performs the existing conjugate gradient methods but also out-performs Quasi-Newton methods that are currently the most efficient methods for solving medium size unconstrained optimization problems.

It can be seen from the results obtained for the Beta Test Hybrid method that is described in Chapter 4, that this method is the only one out of the Hybrids discussed so far that did not use any extra CPU time to achieve its improvement over the methods of Fletcher-Reeves and Polak-Ribière. Moreover, the Beta Test Hybrid method was as efficient as the Angle Test Hybrid method and was only slightly less efficient than Hybrid 2. However,

condition (4.3.6), used as a switching criterion for the Beta Test Hybrid algorithm, cannot be used directly to ensure the method achieves the limit (3.2.3) when exact line searches are performed and to ensure a descent property holds on all iterations with which it would be possible to prove global convergence of the algorithm when inexact line searches are performed.

The idea to be developed in this chapter is to attempt to impose some weak enough conditions not to destroy the desirable features of computational efficiency and CPU time savings achieved by the Beta Test Hybrid method, in order to make a proof of global convergence possible and possibly to achieve a better computational efficiency for the resulting algorithm. A careful analysis aimed at seeking these conditions that are to be imposed, has led to the development of a very efficient hybrid algorithm that is not only globally convergent in both cases when exact and inexact line searches are performed throughout the algorithm but is also computationally far more efficient than all the conjugate gradient methods described herein. In fact this hybrid conjugate gradient algorithm is also computationally more efficient than Quasi-Newton algorithms on the problems tested.

2. AN EFFICIENT HYBRID CONJUGATE GRADIENT ALGORITHM : HYBRID 3.

2.1 Construction of the Algorithm.

As it was felt in Chapter 4 that the switching criterion of Hybrid 1 (4.2.3) was too restrictive in choosing to use the Polak-Ribière update, the switching criterion of the Beta Test

Hybrid algorithm (4.3.6) is perhaps too permissive in its choice of using the Polak-Ribière update and may therefore allow the use of large values of the Polak-Ribière update that would make the angle between the negative gradient and the search direction too close to $\pi/2$, which is undesirable because such a situation would provide a fairly small reduction in the function value. Therefore, as a first modification to the Beta Test Hybrid algorithm, we shall introduce a positive parameter μ in (4.3.6) instead of σ , such that $\mu > \sigma$, in order to be able to control the closeness of the angle in question to $\pi/2$ by having more flexibility in choosing the best value of this parameter μ , that leads to better computational results. Thus, instead of using (4.3.6) as a switching criterion, we shall use the following condition:

$$\beta^{(k)}(P.R) \leq \frac{1}{2\mu} \frac{\|g^{(k+1)}\|^2}{\|g^{(k)}\|^2}, \quad \mu > \sigma .$$
 (5.2.1)

This modification should make the algorithm more efficient computationally for it uses the best of the values of the Polak-Ribière updates and replaces the larger ones by a Fletcher-Reeves update, that is in this case necessarily smaller, to bound the angle away from orthogonality. However, with condition (5.2.1) alone, a proof of global convergence of the algorithm still seems far from being easy to obtain if possible at all. We shall now seek some further conditions that will make a global convergence proof obtainable.

Let us put ourselves in the situation where we wish to prove global convergence for the Beta Test Hybrid algorithm described in Chapter 4 with (4.3.6) replaced by (5.2.1) with exact line searches, and investigate what the problem is that makes this proof not obtainable. Following the proofs given for Hybrid 1 and Hybrid 2 we have:

From the definition of $s^{(k)}$ and exact line search, we deduce the equation:

$$\| s^{(k)} \|^{2} = \| g^{(k)} \|^{2} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2} .$$
 (5.2.2)

If we also impose the condition that $\sigma < \mu < \frac{1}{2}$ then both the Fletcher-Reeves and the Polak-Ribière updates satisfy:

$$0 \leq \beta^{(k-1)} \leq \frac{1}{2\mu} \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2} .$$
 (5.2.3)

It then follows that:

$$\| s^{(k)} \|^{2} \leq \left(\frac{1}{2\mu} \right)^{2k} \| g^{(k)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2} .$$
 (5.2.4)

At this point we would like to establish an inequality similar to that of (4.2.22). The problem in (5.2.4) is that the coefficient $\left(\frac{1}{2\mu}\right)^{2k}$ is k dependent as opposed to the coefficient $\left(\frac{1+\sigma}{1-\sigma}\right)$ in (4.2.22) which is constant for all k. However, we note that one could control the decrease in $\|g^{(k)}\|^2$ by the decrease of $(2\mu)^k$. In other words one could impose the condition that $\|g^{(k)}\|^2$ although not necessarily monotonically decreasing, should not exceed some prescribed multiple of $(2\mu)^k$. This is in fact a quite reasonable condition to impose because all it means is that the solution path generated by the algorithm should not move too far away from the stationary point once a certain level of closeness is achieved by the current estimate. If at any iteration it is found that $\|g^{(k)}\|^2$ is greater than $(2\mu)^k$ the algorithm should be restarted with a steepest descent direction to restore conjugacy that might have been lost as a consequence of this feature. The condition to be imposed is then the following:

$$\lambda \| g^{(k+1)} \|^2 \leq (2\mu)^{k+1} , \frac{1}{2} > \mu > \sigma$$
 (5.2.5)

for some $\lambda > 0$.

Consequently, we suggest the use of the following algorithm to compute $\beta^{(k)}$ in (3.1.7) at each iteration

Step 1 : If (5.2.5) holds go to Step 2. Otherwise $\beta^{(k)} = 0$, return.

Step 2: If $\beta^{(k)}(P.R) < 0$, then $\beta^{(k)} = \beta^{(k)}(F.R)$, return. • Otherwise go to Step 3.

Step 3 : If (5.2.1) holds, then $\beta^{(k)} = \beta^{(k)}(P.R)$, return. Otherwise $\beta^{(k)} = \beta^{(k)}(F.R)$, return.

Note that we have missed out Step 2 of algorithm (4.3.7) because the set of numbers that satisfy (5.2.1) includes those that satisfy (4.2.3) and it is therefore not necessary to check whether (4.2.3) is satisfied. This is so, of course, because $\mu < \frac{1}{2}$. The case $\mu \ge \frac{1}{2}$ however, is covered in Hybrid 1, described in Chapter 4, which did not prove to be very efficient computationally. In what follows, we shall show that when this Hybrid algorithm 147

(5.2.6)

Hybrid 3, is used to find the least value of a general twice continuously differentiable function f(x) with bounded level set (3.1.10), a descent property holds on all iterations and the limit (3.2.3) is achieved. Proofs are given for both cases when an exact line search and when an inexact line search satisfying (3.1.4) and (3.1.5) are used.

2.2 Descent Property and Global Convergence of Hybrid 3.

2.2.1 The Case of Exact Line Search.

(a) Descent Property.

This follows from the fact that a descent property holds on all iterations for both the Fletcher-Reeves and the Polak-Ribière methods when the line search is exact, which has already been shown in (3.2.2) and from the fact that a steepest descent direction, by definition obviously satisfies the descent property (3.1.6).

(b) Global Convergence.

Let us now assume that f(x) is twice continuously differentiable, that the level set (3.1.10) is bounded and that an exact line search is performed at each iteration of the algorithm using (5.2.6) to compute its update $\beta^{(k)}$ and show that these conditions are sufficient to provide the limit (3.2.3) for Hybrid 3.

Theorem 5.2.1:

If f(x) is twice continuously differentiable, if the level set (3.1.10) is bounded and if $\alpha^{(k)}$ satisfies (3.1.3) on all iterations, then the limit (3.2.3) is achieved by Hybrid 3.

Proof:

The method of proof to be followed here is similar to that given by Powell (1983) for the global convergence of the Fletcher-Reeves method.

From the definition of s^(k) and exact line search, we deduce the equation:

$$\|s^{(k)}\|^2 = \|g^{(k)}\|^2 + \beta^{(k-1)^2} \|s^{(k-1)}\|^2$$

Because $\mu < \frac{1}{2}$, then also $\beta^{(k-1)}(F.R) \leq \frac{1}{2\mu} \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2}$ and

therefore all betas computed from (5.2.6) satisfy:

$$0 \leq \beta^{(k-1)} \leq \frac{1}{2\mu} \frac{\|g^{(k)}\|^2}{\|g^{(k-1)}\|^2} .$$
 (5.2.7)

It therefore follows that:

$$\| s^{(k)} \|^{2} \leq \left(\frac{1}{2\mu} \right)^{2k} \| g^{(k)} \|^{4} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2} .$$
 (5.2.8)

Note that condition (5.2.5) holds on all iterations where a restart has not been made and therefore for these iterations we have:

$$\| s^{(k)} \|^{2} \leq \frac{1}{\lambda^{2}} \sum_{\ell=1}^{k} \| g^{(\ell)} \|^{-2}$$
 (5.2.9)

For those iterations where a restart has been made, we have:

$$\|s^{(k)}\|^2 = \|g^{(k)}\|^2 .$$
 (5.2.10)

Therefore, if (3.2.3) is not true, then there exists a constant ε , say, such that:

$$\|g^{(k)}\| \ge \varepsilon > 0$$
 for all k (5.2.11)

and hence (5.2.9) gives:

$$\|s^{(k)}\| \leq ck$$
,

where c is a positive constant. From the definition of $\alpha^{(k-1)}$ and $s^{(k)}$, it follows that the directional derivatives

$$d^{(k)} = s^{(k)} g^{(k)} / (\|s^{(k)}\| \cdot \|g^{(k)}\|)$$
 (5.2.12)

can be written:

$$d^{(k)} = - \|g^{(k)}\| / \|s^{(k)}\|$$

and because $\|g^{(k)}\|$ is also bounded above in the level set (3.1.10) we have:

$$d^{(k)^{2}} \begin{cases} \ge c_{1}^{k} & \text{if (5.2.9) is true} \\ = 1 & \text{if (5.2.10) is true} \end{cases}$$

which clearly implies that the series $\sum_{k} d^{(k)^{2}}$ is divergent. On the other hand, following Powell's proof for the global convergence of the Fletcher-Reeves method given in Chapter 3, Subsection 2.1, by letting Ω be an upper bound on the induced matrix norms { $\|\nabla^{2} f(x)\|$; x in the level set (3.1.10)}, we obtain:

$$f(x) \leq f(x^{(k)}) + (x - x^{(k)})^{T} g^{(k)} + \frac{1}{2}\Omega ||x - x^{(k)}||^{2}$$
 (5.2.13)

for any x in the level set (3.1.10), which after some considerations of rates of change of first derivatives gives the inequality:

$$f(x^{(k+1)}) \leq f(x^{(k)}) - d^{(k)^2} \frac{\|g^{(k)}\|^2}{2\Omega}$$
 (5.2.14)

The details of these considerations can be found in Subsection 2.1 of Chapter 3. Thus, because f(x) is bounded below in the level set (3.1.10), the series:

$$\sum_{k} d^{(k)^{2}} \|g^{(k)}\|^{2}$$
(5.2.15)

is convergent. But, because of (5.2.11), this contradicts the fact that $\sum_{k} d^{(k)^{2}}$ is divergent established above. Because this contradiction arises from the assumption that (5.2.11) is true, it therefore follows that (5.2.11) is false and the limit (3.2.3) must then be achieved. The proof is thus complete.

2.2.2 The Case of Inexact Line Search.

In what follows, Hybrid 3 is shown to have a descent property and to be globally convergent when an inexact line search satisfying (3.1.4) and (3.1.5) is performed. The methods of proof to be followed here are similar to those given by the Al-Baali (1985) for the Fletcher-Reeves method which are reported in Subsection 2.2 of Chapter 3.

(a) Descent Property.

Theorem 5.2.2:

If an $\alpha^{(k)}$ is calculated that satisfies (3.1.4) with $\sigma \in (0, \frac{1}{2})$ for all k such that $g^{(k)} \neq 0$, then the descent property (3.1.6) holds for all such k when Hybrid 3 is used.

Proof:

The method of proof is to show by induction that the inequalities:

$$-\sum_{j=0}^{k-1} \left(\frac{\sigma}{2\mu}\right)^{j} \leq \frac{g^{(k)}}{\|g^{(k)}\|^{2}} \leq -2 + \sum_{j=0}^{k-1} \left(\frac{\sigma}{2\mu}\right)^{j}$$
(5.2.16)

hold for all k such that $g^{(k)} \neq 0$. It will then follow that the descent property (3.1.6) holds for all such k.

(5.2.16) is clearly satisfied for k = 1. We now assume that it is true for any k \ge 1. Since $\mu > \sigma$ we have $\sigma/2\mu < \frac{1}{2}$. Therefore since

$$\sum_{j=0}^{k-1} \left(\frac{\sigma}{2\mu}\right)^{j} < \sum_{j=0}^{\infty} \left(\frac{\sigma}{2\mu}\right)^{j} = \frac{1}{1 - \frac{\sigma}{2\mu}} , \qquad (5.2.17)$$

it is clear that the right-hand side of (5.2.16) is negative and hence the descent property (3.1.6) is satisfied on iteration k. It follows from the definition of s^(k+1) (3.1.7) that:

$$\frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^2} = -1 + \beta^{(k)} \frac{g^{(k+1)} s^{(k)}}{\|g^{(k+1)}\|^2} .$$
 (5.2.18)

Now, using (3.1.4) and (5.2.18) we obtain:

$$-1 + \sigma \beta^{(k)} \frac{g^{(k)} s^{(k)}}{\|g^{(k+1)}\|^{2}} \leq \frac{g^{(k+1)} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 - \sigma \beta^{(k)} \frac{g^{(k)} s^{(k)}}{\|g^{(k+1)}\|^{2}}.$$
(5.2.19)

Then using (5.2.7) and (5.2.19) we obtain:

$$-1 + \left(\frac{\sigma}{2\mu}\right) \frac{\binom{(k)^{T}}{g} \binom{(k)}{s}}{\|g^{(k)}\|^{2}} \leq \frac{\binom{(k+1)^{T}}{s} \binom{(k+1)}{s}}{\|g^{(k+1)}\|^{2}} \leq -1 - \left(\frac{\sigma}{2\mu}\right) \frac{\binom{(k)^{T}}{g} \binom{(k)}{s}}{\|g^{(k)}\|^{2}}$$

which by using the induction hypothesis (5.2.16) becomes:

$$-1 - \left(\frac{\sigma}{2\mu}\right) \sum_{j=0}^{k-1} \left(\frac{\sigma}{2\mu}\right)^{j} \leq \frac{g^{(k+1)T} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -1 + \left(\frac{\sigma}{2\mu}\right) \sum_{j=0}^{k-1} \left(\frac{\sigma}{2\mu}\right)^{j}$$

which again by using the argument developed in (3.2.13) replacing σ by $\frac{\sigma}{2\mu}$ we obtain:

$$-\sum_{j=0}^{k} \left(\frac{\sigma}{2\mu}\right)^{j} \leq \frac{g^{(k+1)^{T}} s^{(k+1)}}{\|g^{(k+1)}\|^{2}} \leq -2 + \sum_{j=0}^{k} \left(\frac{\sigma}{2\mu}\right)^{j}$$

which is (5.2.16) with k replaced by k+1. Thus the induction is complete.

A consequence of this descent property is the following global convergence result.

(b) Global Convergence.

Theorem 5.2.3:

If the level set (3.1.10) is bounded, if f(x) is twice continuously differentiable, if $\alpha^{(k)}$ is any value satisfying (3.1.4) and (3.1.5) with $\rho < \sigma < \frac{1}{2}$ and if $\beta^{(k)}$ is computed from (5.2.6) at each iteration, then the limit (3.2.3) is achieved.

Proof:

From the definition of $s^{(k)}$ in (3.1.7) we obtain:

$$\|s^{(k)}\|^{2} = \|g^{(k)}\|^{2} - 2\beta^{(k-1)}g^{(k)}s^{(k-1)} + \beta^{(k-1)}\|s^{(k-1)}\|^{2}.$$
(5.2.20)

It is shown in Theorem 5.2.2 that the descent property (3.1.6)

holds for $\sigma \in (0, \frac{1}{2})$. Therefore from (3.1.4), (5.2.16) and (5.2.17), it follows that:

$$|g^{(k)^{T}}s^{(k-1)}| \leq -\sigma g^{(k-1)^{T}}s^{(k-1)} \leq \frac{\sigma}{1-\frac{\sigma}{2\mu}} \|g^{(k-1)}\|^{2}$$

which can be substituted into (5.2.20) to give:

$$\| \mathbf{s}^{(k)} \|^{2} \leq \| \mathbf{g}^{(k)} \|^{2} + \frac{2\sigma}{1 - \frac{\sigma}{2\mu}} \beta^{(k-1)} \| \mathbf{g}^{(k-1)} \|^{2} + \beta^{(k-1)^{2}} \| \mathbf{s}^{(k-1)} \|^{2}$$

and finally using (5.2.7) we obtain:

$$\| s^{(k)} \|^{2} \leq \| g^{(k)} \|^{2} + \frac{\frac{\sigma}{\mu}}{1 - \frac{\sigma}{2\mu}} \| g^{(k)} \|^{2} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2}$$
$$= \left(\frac{1 + \frac{\sigma}{2\mu}}{1 - \frac{\sigma}{2\mu}} \right) \| g^{(k)} \|^{2} + \beta^{(k-1)^{2}} \| s^{(k-1)} \|^{2} .$$

It then follows by induction that:

$$\| \mathbf{s}^{(\mathbf{k})} \|^{2} \leq \left(\frac{1 + \frac{\sigma}{2\mu}}{1 - \frac{\sigma}{2\mu}} \right) \left(\frac{1}{2\mu} \right)^{2\mathbf{k}} \| \mathbf{g}^{(\mathbf{k})} \|^{4} \sum_{\ell=1}^{\mathbf{k}} \| \mathbf{g}^{(\ell)} \|^{-2}$$

Because (5.2.5) holds on all iterations where a restart has not been made, we therefore obtain for these iterations:

$$\|s^{(k)}\|^{2} \leq \left(\frac{1+\frac{\sigma}{2\mu}}{1-\frac{\sigma}{2\mu}}\right) \cdot \frac{1}{\lambda^{2}} \cdot \sum_{\ell=1}^{k} \|g^{(\ell)}\|^{-2} \quad (5.2.21)$$

For those iterations where a restart has been made on the other hand we have:

$$\| s^{(k)} \|^2 = \| g^{(k)} \|^2$$
 (5.2.22)

Now, if (3.2.3) is not true, then (5.2.11) is true, and therefore (5.2.21) gives:

$$\| s^{(k)} \|^2 \leq c_2^k$$

where c₂ is a positive constant. From (5.2.16) and (5.2.17) it follows that:

$$\cos^{2}(\theta^{(k)}) \geq \left(\frac{1+\frac{\sigma}{\mu}}{1-\frac{\sigma}{2\mu}}\right)^{2} \frac{\|g^{(k)}\|^{2}}{\|s^{(k)}\|^{2}} , \qquad (5.2.23)$$

where $\theta^{(k)}$ is the angle between the steepest descent direction $-g^{(k)}$ and the search direction $s^{(k)}$ and where $\cos(\theta^{(k)})$ is as defined in (3.2.6). Therefore because $\|g^{(k)}\|$ is also bounded above in the level set (3.1.10) we obtain from (5.2.23):

$$\cos^{2}(\theta^{(k)}) \begin{cases} \geqslant c_{3}^{k} & \text{if (5.2.21) is true} \\ = 1 & \text{if (5.2.22) is true} \end{cases}$$

which clearly implies that the series $\sum_{k} \cos^{2}(\theta^{(k)})$ diverges. However, it is possible to contradict this result using the line search conditions. If Ω is an upper bound on $\|\nabla^{2} f(x)\|$ for x in the level set (3.1.10), we have:

$$g^{(k+1)^{T}} s^{(k)} \leq g^{(k)^{T}} s^{(k)} + \Omega \alpha^{(k)} \|s^{(k)}\|^{2}$$

Thus, by using (3.1.4) we obtain:

$$\alpha^{(k)} \ge -\frac{1-\sigma}{\Omega} \cdot \frac{g^{(k)} s^{(k)}}{\|s^{(k)}\|^2},$$

which can be substituted in (3.1.5), and by using (3.1.6) and

(3.2.6) it follows that:

$$f(x^{(k+1)}) \leq f(x^{(k)}) - K \frac{\left(g^{(k)} s^{(k)}\right)^{2}}{\|s^{(k)}\|^{2}}$$

=
$$f(x^{(k)}) - K || g^{(k)} ||^2 \cos^2(\theta^{(k)})$$

where $K = \rho(1-\sigma)/\Omega > 0$. Thus since f(x) is bounded in the level set (3.1.10), $\sum_{k} \|g^{(k)}\|^{2} \cos^{2}(\theta^{(k)})$ is convergent, and because $\|g^{(k)}\|$ is bounded below, this contradicts the fact that $\sum_{k} \cos^{2}(\theta^{(k)})$ is divergent established above. Since this contradiction arises from the assumption that (3.2.3) is not true, then the limit (3.2.3) must be achieved and Hybrid 3 is globally convergent when an inexact line search is used satisfying (3.1.4) and (3.1.5).

It is important to note that in contrast to the proofs given in Chapter 4 for Hybrid 1 and Hybrid 2, the proofs given in this chapter for the descent property and global convergence of Hybrid 3 do not use the fact that the quantity $\beta^{(k)}(P.R)$ used in (5.2.6) actually takes the value (3.1.9) of Polak-Ribière. Therefore, one can use any desired conjugate gradient formula instead of (3.1.9) in (5.2.6) without affecting the validity of these proofs.

2.3 Computational Performance of Hybrid 3.

Here again, the N.A.G. routine EØ4DBF, in which the computation of the update $\beta^{(k)}$ was modified to compute $\beta^{(k)}$ as defined in (5.2.6), was used to test Hybrid 3 on the same test problems on which all the methods described so far were tested. These test problems are described in the final Chapter entitled "Discussion and Conclusions". Testing the method on any of these problems involves running the program 26 times (once for every different number of variables), each run producing a set of results containing the number of variables, the number of iterations, the number of function evaluations, the index of computational labour, the CPU time needed for the run and the function value at the minimum. These extensive sets of results for Hybrid 3 are given in Appendix 2, Tables (2.15.i) for i = 1,2,3,...,7, whereas the overall results with the comparison of the figures obtained by Hybrid 3 against those obtained by both the Fletcher-Reeves and Polak-Ribière methods are given in Appendix 3, Table (3.15).

Hybrid 3 uses two scalars λ and μ . Although different values of these scalars work better on different types of problems, it was found by trying different values of these scalars that Hybrid 3 achieves its best overall results when $\lambda = 10^{-8}$ and $\mu = 0.1$. The overall total figures obtained with these values of these two scalars, represent 25%, 29% and 24% of the overall total figures obtained by the Fletcher-Reeves method, in terms of: number of iterations (NI), number of function evaluations (NF) and index of computational labour (NC) respectively, and represent 47%, 51% and 44% of the overall total figures obtained by the Polak-Ribière method respectively. This means that Hybrid 3 achives spectacular improvements over both the Fletcher-Reeves and the Polak-Ribière of 75%, 71% and 76%, and of 53%, 49% and 56% respectively, in terms of NI, NF and NC respectively. Furthermore, because of these great improvements of Hybrid 3 over the Fletcher-Reeves and the Polak-Ribière methods we carried on the testing to see

whether Hybrid 3 can outperform Quasi-Newton methods. We used the N.A.G. routine EØ4KBF to obtain the results by the Quasi-Newton described in Gill and Murray (1972). This routine was run on all the test problems considered with up to 100 variables which reduces the number of problems from 182 cases to 63. This is to avoid the computational inefficiency of Quasi-Newton methods that could occur for problems with large dimensions. The results obtained by EØ4KBF on each case separately are given in Appendix 2, Tables (2.18.i) for i = 1, 2, ..., 7 whereas the overall results and the comparison of the figures obtained by H3 and EØ4KBF are given in Appendix3, Table (3.21). These results show that Hybrid 3 does indeed outperform this Quasi-Newton method by 33% in terms of the index of computational labour which is a great achievement. Further discussions of these results are given in the final Chapter "Discussion and Conclusions".

3. AN EFFICIENT RESTARTING PROCEDURE.

3.1 Defining the Procedure.

When minimizing a non quadratic function, it is usually suggested that a conjugate gradient method should be restarted at regular intervals. Fletcher and Reeves (1964) for example, suggest a restart after every n+1 iterations where n is the dimension of f. Thus when a region is entered where the objective function is very nearly quadratic, accumulated errors from previous iterations due to effects of inaccurate line searches and loss of conjugacy, will not interfere with the expected good behaviour of the algorithm.

However, when n is very large, restarting at regular intervals has very little effect. Various restarting procedures for conjugate gradient methods that take account of the objective function being minimized have been suggested in the literature amongst which are the procedures of Powell (1977) and Shanno (1985). In what follows we describe a different procedure that proved to be computationally very efficient.

First we note that condition (5.2.5) used in Hybrid 3 puts an iteration dependent upper bound on how far the solution path can move away from the stationary point that it is approaching. Therefore if one restarts the algorithm when this condition is no longer satisfied, this should re-establish the normal behaviour of the algorithm. Moreover, when $\beta^{(k)}$ takes the value in (3.1.9), condition (5.2.1) in Hybrid 3 implies:

$$-g^{(k+1)^{T}}g^{(k)} \leq \left(\frac{1-2\mu}{2\mu}\right) \|g^{(k+1)}\|^{2} . \qquad (5.3.1)$$

And when $\beta^{(k)}(P.R) \ge \beta^{(k)}(F.R)$ we obtain:

$$0 \leq -g^{(k+1)^{T}} g^{(k)} \leq \left(\frac{1-2\mu}{2\mu}\right) \|g^{(k+1)}\|^{2} . \qquad (5.3.2)$$

By substituting (5.2.5) into (5.3.2) we obtain:

$$0 \leq -g^{(k+1)} g^{(k)} \leq \lambda (1 - 2\mu) (2\mu)^{k}$$

and therefore (5.2.1) together with (5.2.5) put a similar upper bound on the loss of orthogonality between successive gradients due to inexact line searches. Consequently it seems logical to impose these two conditions as restarting criteria for conjugate gradient methods. These criteria not only provide computational improvements of conjugate gradient methods as will be seen in Subsection 3.2 of this chapter, but they also make a descent property hold and a global convergence proof possible for any conjugate gradient method with a non-negative update β , for both cases when either an exact line search or an inexact line search is used.

3.2 Computational Performance of the New Restarting Procedure.

The program used to test these criteria is again the N.A.G. routine EØ4DBF where a modification of its original restart every n+1 iterations, was made to implement these new criteria. We used these criteria with the Fletcher-Reeves method and with that of Polak-Ribière and tested them on all the test problems discussed in this thesis. The extensive results for each of the 182 cases considered, separately are given in Appendix 2, Tables (2.16.i) i = 1,2,...,7 for the Fletcher-Reeves method and Tables (2.17.i) i = 1.2,...,7 for the Polak-Ribière method, whereas the overall results with the comparison of the figures obtained by the Fletcher-Reeves method with new restarts against those obtained by both straight-forward Fletcher-Reeves and Polak-Ribière methods that restart every n+1 iterations are given in Appendix 3, Table (3.16) and the overall results with the comparison of the figures obtained by the Polak-Ribière method with new restarts against those obtained by both straight-forward Fletcher-Reeves and Polak-Ribière methods that restart every n+1 iterations are given in the same appendix: Appendix 3, Table (3.17). These results show that when these

restart criteria are used for the Fletcher-Reeves method they better the method by 72%, 68% and 63% in terms of NI, NF and NC respectively and they better the Polak-Ribière method by 47%, 43% and 51% in terms of NI, NF and NC, whereas when they are used for the Polak-Ribière method, they better the method by 55%, 49% and 57% in terms of NI, NF and NC respectively, and they better the Fletcher-Reeves method by 76%, 72% and 76% in terms of NI, NF and NC respectively. These results are further discussed in the "Discussion and Conclusions" Chapter.

Chapter 6

Discussion and Conclusions

1. RESULTS DESCRIPTION.

The program used to test all the conjugate gradient methods described in this thesis is the N.A.G. routine EØ4DBF in which the computation of $\beta^{(k)}$ had been modified accordingly. For Hybrid 3 and when using the new restarting criteria of Chapter 5, further modifications in EØ4DBF which originally restarts every n+1 iterations, were made to allow for the setting of $\beta^{(k)}$ to zero when required by the conditions of Hybrid 3 or according to the new restarting criteria. As to testing a variable metric method for comparison with the new hybrid conjugate gradient methods, we used the N.A.G. routine EØ4KBF which contains the quasi-Newton method as described by Gill and Murray (1972).

The test functions used for comparison purposes are the following well known test functions:

Problem 1 : "The Extended Rosenbrock Test Function".

$$F = \sum_{i=1}^{n/2} \left[100(x_{2i} - x_{2i-1}^2)^2 + (1 - x_{2i-1})^2 \right] .$$

$$n = 2, 20, 40, 60, \dots, 440, 460, 480, 500.$$

$$x^{(0)} = (-1.2, 1, -1.2, 1, \dots, -1.2, 1)^{T}.$$

Problem 2 : "The Extended Wood Test Function".

$$F = \sum_{i=1}^{n/4} \left[100 (x_{4i-3}^2 - x_{4i-2})^2 + (x_{4i-3} - 1)^2 + 90 (x_{4i-1}^2 - x_{4i})^2 + (1 - x_{4i-1})^2 + 10.1 \{ (x_{4i-2} - 1)^2 + (x_{4i} - 1)^2 \} + 19.8 (x_{4i-2} - 1) \right]$$

$$\cdot (x_{4i} - 1)].$$

n = 4, 20, 40, 60,..., 440, 460, 480, 500.

$$x^{(o)} = (-3, -1, -3, -1, ..., -3, -1, -3, -1)^{T}.$$

 $\frac{\text{Problem 3}}{\text{F}} : \text{"The Extended Miele and Cantrell Test Function".}}$ $F = \sum_{i=1}^{n/4} \left[(\exp(x_{4i-3}) - x_{4i-2})^2 + 100(x_{4i-2} - x_{4i-1})^6 + \left\{ \tan(x_{4i-1} - x_{4i}) \right\}^4 + x_{4i-3}^8 \right].$ $n = 4, 20, 40, 60, \dots, 440, 460, 480, 500.$ $x^{(0)} = (1, 2, 2, 2, 1, 2, 2, 2, \dots, 1, 2, 2, 2)^T.$ Problem 4 : "The Extended Powell Test Function".

$$F = \sum_{i=1}^{n/4} \left[(x_{4i-3} + 10x_{4i-2})^2 + 5(x_{4i-1} - x_{4i})^2 + (x_{4i-2} - 2x_{4i-1})^4 + 10(x_{4i-3} - x_{4i})^4 \right].$$

$$n = 4^{\circ}, 20, 40, 60, \dots, 440, 460, 480, 500.$$

$$x^{(0)} = (3, -1, 0, 1, 3, -1, 0, 1, \dots, 3, -1, 0, 1)^{T}.$$

$$F = \sum_{i=1}^{n/10} \left[(1 - x_{10i-g})^2 + (1 - x_{10i})^2 + \sum_{j=10i-g}^{10i-1} (x_j^2 - x_{j+1})^2 \right]$$

n = 10, 20, 40, 60,..., 440, 460, 480, 500.

$$x^{(o)} = (-2, -2, \dots, -2)^{T}.$$

Problem 5 : "The Extended Dixon Test Function".

Problem 6 : "The Extended Beale Test Function".

$$F = \sum_{i=1}^{n/2} \left[\left\{ 1.5 - x_{2i-1}(1 - x_{2i}) \right\}^2 + \left\{ 2.25 - x_{2i-1}(1 - x_{2i}^2) \right\}^2 + \left\{ 2.625 - x_{2i-1}(1 - x_{2i}^3) \right\}^2 \right].$$

 $n = 2, 20, 40, 60, \ldots, 440, 460, 480, 500.$

$$\mathbf{x}^{(0)} = (1, 0.8, 1, 0.8, \dots, 1, 0.8)^{\mathrm{T}}.$$

Problem 7 : "The Extended Engrall Test Function".

$$F = \sum_{i=1}^{n/2} \left[x_{2i-1}^4 + x_{2i}^4 + 2x_{2i-1}^2 x_{2i}^2 - 4x_{2i-1} + 3 \right] .$$

$$n = 2, 20, 40, 60, \dots, 440, 460, 480, 500.$$

$$x^{(0)} = (0.5, 2, 0.5, 2, \dots, 0.5, 2)^{T}.$$

Testing a method on any of these problems involves running the corresponding version of the program 26 times, each run producing a set of results containing the number of variables (NV), the number of iterations (NI), the number of function evaluations (NF), the index of computational labour (NC), the CPU time needed to reach the minimum and the function value at the minimum (FV). These extensive sets of results for each method, each problem and each number of variables considered are given in Appendix 2. A summarized version of these results, that'is more practical for comparison, is given in Appendix 3. These latter results are obtained by considering for each problem, the totals of the 26 values for each of the numbers of iterations, function evaluations, indices of computational labour and cpu times achieved by each method, computing the ratios of these totals for each of the new methods over those of the existing ones and finally by considering the grand totals (of the totals, for each problem) and by computing the overall ratios in the same manner as above. In this way, it is possible to compare the performance of each of the new methods with those of the existing ones on each problem separately, and overall.

Let the Rosenbrock, Wood, Miele and Cantrell, Powell, Dixon, Beale and Engrall test functions be problems 1, 2, 3, 4, 5, 6 and 7 respectively and let the F.R, the P.R, the Powell hybrid, ORIG1, ORIG2, Hybrid 1, the Shanno, the ATH ($\tau = 0.1$), ATH ($\tau = 0.01$), ATH ($\tau = 0.001$), the BTH, Hybrid 2 ($\tau = 10^{-4}$), Hybrid 2 ($\tau = 10^{-6}$), Hybrid 2 ($\tau = 10^{-8}$), Hybrid 3, F.R with new restart, P.R with new restart and the Quasi-Newton method be methods 1, 2, 3,..., 16, 17 and 18 respectively. The tables in Appendix 2 containing the extensive sets of results are labelled Tables (2-i-j) where 2 denotes the Appendix number, i denotes the method (i = 1,2,...,18) and j denotes the problem (j = 1,...,7), whereas the tables in Appendix 3 containing the summarized results are labelled Tables (3-i) where 3 denotes the Appendix number and i = 1,...,17 for the 17 first tables denotes the corresponding method. For the Quasi-Newton method (method 18) a different setting of the tables is used because for this method the test problems are used up to 160 variables instead of 500 variables. Using the 7 test problems up to 160 variables, Table (3-18) contains the summarized results of the Fletcher-Reeves, Table (3-19) contains those of the P.R method and their comparison with the results of F.R, Table (3-20) contains the summarized results of the Quasi-Newton method and their comparison with those of both the F.R and P.R methods whereas Table (3-21) contains the results of Hybrid 3 compared to the F.R, the P.R and the Q.N. methods.

2. DISCUSSIONS OF THE RESULTS.

Let us now consider the computational performances of all the conjugate gradient methods dealt with in this thesis, on each problem separately and overall.

First however, we shall describe and compare the performances of the Fletcher-Reeves and Polak-Ribière methods on the seven extended test problems described above. Then all the other methods will be compared with these two methods.

The results obtained for the Fletcher-Reeves and Polak-Ribière methods do indeed confirm the well-known fact that in numerical computations, the Polak-Ribière algorithm is far more successful than that of the Fletcher-Reeves. Our results show that, out of the 182 cases considered (7 test problems each with

26 different numbers of variables) only in 17 cases was the Fletcher-Reeves performance as good as or slightly better than that of the Polak-Ribière. On all the other cases the Polak-Ribière method proved to be far more successful. The greatest improvements of the Polak-Ribière method over that of Fletcher-Reeves were obtained especially on Problems 1, 5 and 6 where the respective improvements were of 72%, 77% and 88% in terms of the NI, 65%, 75% and 79% in terms of the NF, 66%, 79% and 81% in terms of the NC, and, 66%, 79% and 83% in terms of cpu time. The lowest improvement however, was obtained when the methods were tested on the extended Powell test problem. Problem 4 where for the same CPU time the Polak-Ribière method achieved 14%. 13% and 11% improvements over the method of Fletcher-Reeves in terms of the NI, NF and NC respectively. Considering all problems resulting in 182 cases, the Polak-Ribière method achieved overall improvements over the method of Fletcher-Reeves of 47% 44%, 45% and 45% in terms of NI, NF, NC and CPU respectively. These comparison results are given in Appendix 3, Table 3-2.

Another method considered in this thesis was the method extracted from Powell's idea of avoiding negative betas in the Polak-Ribière method. Although this method has failed to better the straight-forward Polak-Ribière method on problems 3, 6 and 7 it did nevertheless achieve some improvements on the other problems. Its best improvement was on problem 2 where it bettered the original method by 13%, 13%, 17% and 24% in terms of the NU, NF, NC and cpu time respectively. However, its overall improvement was of 11%, 10%, 12% and 18% in terms NI, NF, NC and cpu time respectively. The results of this method compared with those of the Fletcher-Reeves and those of the Polak-Ribière methods are given in Appendix 3, Table 3-3.

As to the method suggested by Shanno that uses an angle test to decide when a conjugate gradient algorithm should be restarted, this method using the Polak-Ribière update to compute $\beta^{(k)}$ achieved better results than Powell's algorithm above but this improvement was achieved at the expense of some extra cpu time. The overall improvement achieved by Shanno's algorithm over the straight-forward Polak-Ribière method are as follows: 13%. 12%, 13% and 3% in terms of NI, NF, NC and cpu time. Therefore it used 15% extra cpu time as compared to Powell's algorithm, to achieve extra 2%, 2% and 1% improvements in terms of NI, NF and NC respectively over the Polak-Ribière method. The results of this method compared with those of the methods of Fletcher-Reeves and Polak-Ribière are given in Appendix 3, Table 3-7.

Having discussed the results of the existing conjugate gradient methods and of those constructed from ideas from outside this thesis, we shall now turn to the discussion of the hybrid conjugate gradient methods that we have constructed in this thesis. We shall consider the performances of these hybrids on each problem separately and overall.

The Results Obtained for Problem 1. ORIG1 Method : Only in the case of 2 variables, was the performance of the Fletcher-Reeves method slightly better than

that of ORIG1 hybrid method. On all the other 25 cases considered for Problem 1, ORIG1 performed much better than the Fletcher-Reeves method. When compared with the results achieved by the Polak-Ribière method too, only on a few cases (NI = 120 and NI = 420 for example) was the performance of the P.R method better than that of ORIG1 and in most other cases ORIG1 has outperformed the P.R method. The case NV = 2 is interesting. We can see that for one extra function evaluation needed by ORIG1 as compared with the P.R method, ORIG1 obtains an approximation to the function value at the minimum FV = 0, which is 8 decimals better than that obtained by the P.R method. The P.R method obtains FV = 0.5894×10^{-19} whereas ORIG1 obtains FV = 0.1831×10^{-27} . Considering all the 26 cases of Problem 1, ORIG1 betters the performance of the F.R method by 74%. 67%, 68% and 70% in terms of NI, NF, NC and CPU respectively and betters that of the P.R method by 7%, 7%, 7% and 12% in terms of NI, NF, NC and CPU respectively. These improvements are greater than the improvements achieved by both Powell's method and Shanno's method. The results obtained by ORIG1 hybrid method on Problem 1 are given in Appendix 2, Table 2-4-1 and the comparison of these results with the F.R and P.R methods is given in Appendix 3, Table 3-4.

ORIG2 Method : Here again, only on a few cases was the method of F.R or that of P.R slightly better than ORIG2. On all the other cases ORIG2 out-performed both methods. When considering all the cases of Problem 1, ORIG2 performed more or less as well as ORIG1. It bettered the performance of the F.R method by

74%, 67%, 68% and 69% in terms of NI, NF, NC and CPU respectively and bettered the performance of the P.R method by 5%, 7%, 5% and 6% in terms of NI, NF, NC and CPU respectively. The results obtained by ORIG2 on Problem 1 are given in Appendix 2, Table 2-5-1 and the comparison of these results with those of the F.R and P.R methods is given in Appendix 3, Table 3-5.

Hybrid 1 Method : On Problem 1, only on a few cases (Nv = 400, 440 or 480 for example) was the performance of Hybrid 1 better than that of the F.R method, but it failed to better it overall (see Tables 2-1-1 and 2-6-1 in Appendix 2). Since the P.R method, as was seen above, performed far better than the F.R method, the performance of Hybrid 1 was much worse than that of the P.R method (see Tables 2-2-1 and 2-6-1 in Appendix 2). We have attempted to explain, in Remark 2 of Chapter 4, some of the reasons for which such inefficiency may occur when using Hybrid 1 and have pointed out in particular that one of the disadvantages of Hybrid 1 was that the angle $\theta^{(k)}$ between the negative gradient and the search direction may tend to be too small to get enough decrease in the function value. We also showed in Figure 4-2-2 of Chapter 4 that this undesirable feature is very likely to occur when Hybrid 1 is used to solve the Rosenbrock problem, and suggested the use of Shanno's angle test to allow for more P.R updates to be used. The implementation of Shanno's angle test within Hybrid 1 has resulted in what we called the "Angle Test Hybrid Method" (ATH), and has indeed helped the situation just described a great deal. The results obtained by Hybrid 1 on Problem 1 with its 26 cases,
are given in Appendix 2, Table 2-6-1 and the comparison results of Hybrid 1 with the methods of both F.R and P.R are given in Appendix 3, Table 3-6.

The Angle Test Hybrid (ATH) Method : We can see from Tables 2-8-1, 2-9-1 and 2-10-1 that the use of this angle test does improve the situation described above a great deal. Indeed the Angle Test Hybrid with $\tau = 0.1$ (ATH1), with $\tau = 0.01$ (ATH2) and with $\tau = 0.001$ (ATH3) was respectively 7%, 8% and 7% better than the P.R method in terms of the index of computational labour. These improvements over the P.R method are however achieved at the expense of approximately 8%, 7% and $6\frac{1}{2}$ % extra cpu time respectively. As to their improvements over the F.R method, ATH1, ATH2 and ATH3 were 68%, 68% and 68% better respectively in 63%, 64% and 64% less CPU time. Other values of τ were tried in an attempt to find the best value of τ in the sense the value that provides the greatest improvement in the index of computational labour. The results of these attempts are not given here because it was found that the best value of τ was τ = 0.01 used in ATH2. The results obtained by ATH1, ATH2 and ATH3 on Problem 1 with its 26 cases, are given in Appendix 2, Tables 2-8-1, 2-9-1 and 2-10-1 whereas the comparison results of this method with the three values of τ , with the methods of P.R and F.R are given in Appendix 3, Tables 3-8, 3-9 and 3-10.

The Beta Test Hybrid (BTH) Method: The B.T.H method was constructed in an attempt to avoid the use of the angle test that resulted in the storage of an extra n-dimensional vector

and some more computations on every iteration which lead to some extra cpu time as seen above. The improvements achieved by the ATH method over the P.R method were achieved at the expense of some extra cpu time. The idea was then to find an equivalent condition to the one used in ATH, that is condition 4.3-10. that needs less computation. Condition 4.3.6 did indeed achieve what was required in the sense that it obtained the same improvement in the index of computational labour and instead of using some extra cpu time as ATH did it even needed less. The question of its equivalence with condition 4.3.10 however, remains open. The BTH method was 8% better than the P.R method in terms of the index of computational labour and 5% better in terms of cpu time needed to solve the 26 cases of Problem 1. As to its performance against that of the F.R method on Problem 1, it was 68% better in terms of the index of computational labour and the same percentage better in terms of cpu time. The results achieved by the BTH method on Problem 1 with its 26 cases are given in Appendix 2, Table 2-11-1 and the comparison results comparing the BTH method to both the F.R and P.R methods on Problem 1 are given in Appendix 3, Table 3-11.

Hybrid 2 Method : As it was seen in Chapter 4, condition 4.3.10 ensures a descent property to hold and achieves global convergence of ATH with exact line searches. However, it was not possible to use this condition directly to ensure a descent property to hold with which it would be possible to prove the global convergence of the algorithm when inexact line searches are performed throughout the algorithm. By using both conditions,

4.3.10 and 4.3.6 together as explained in Chapter 4 we derived a new hybrid algorithm that not only achieves some improvements over both the F.R and the P.R methods but also ensures a descent property to hold and achieves global convergence in both cases when either exact or inexact line searches are used throughout the algorithm. Since this algorithm uses condition 4.3.10 in particular various values of the scalar τ were tried in an attempt to find the best value of this parameter. Three values of this parameter were found satisfactory; namely $\tau = 10^{-4}$, $\tau = 10^{-6}$ and $\tau = 10^{-8}$. Even though Hybrid 2 with these three values of τ was some 8%, 8% and 2% better than the P.R method respectively and some 68%, 68% and 67% improvement over the F.R method respectively, in terms of the index of computational labour, it was not, expectedly, the best hybrid in terms of cpu time; the reason being the use of condition 4.3.10. The results of this hybrid with its 3 values of τ on Problem 1 with its 26 cases are given in Appendix 2, Tables 2-12-1, 2-13-1 and 2-14-1 whereas the comparison results are given in Appendix 3, Tables 3-12, 3-13 and 3-14.

Hybrid 3 Method : On Problem 1 in particular, Hybrid 3 was not the best of the hybrids computationally although overall it is. In fact it failed to better the P.R method performance but it was not as bad as Hybrid 1. It could only better the F.R method achieving 68%, 62%, 62% and 62% improvements in terms of NI, NF, NC and CPU respectively. The results of this method on Problem 1 with its 26 cases are given in Appendix 2, Table 2-15-1 and those comparing the method to both the F.R and the P.R method are given in Appendix 3, Table 3-15. F.R and P.R Methods with New Restart : Using the new restarting procedure with the Fletcher-Reeves method did improve the method itself a great deal but did not bring it to compare favourably with the standard Polak-Ribière method. When used with the Polak-Ribière method this procedure failed to better the method on this particular problem. The results of the F.R and the P.R methods with new restart on the 26 cases of Problem 1 are given in Tables 2-16-1 and 2-17-1 respectively, whereas the comparison results with the straight-forward F.R and P.R methods are given in Appendix 3, Tables 3-16 and 3-17 respectively.

The Results Obtained for Problem 2 :

ORIG1 and ORIG2 hybrid methods both achieved some considerable improvements over both the Fletcher-Reeves and the Polak-Ribière methods reducing even the cpu time needed to solve the 26 cases of this particular problem. ORIG2 was however slightly better than ORIG1. ORIG1 achieved 20% improvement in terms of the index of computational labour and 26% improvement in terms of cpu time over the P.R method whereas ORIG2 achieved 22% and 24% respectively over the same method. As to their comparison with the Fletcher-Reeves method ORIG1 achieved 63% improvement in terms of both the index of computational labour and cpu time whereas ORIG2 achieved 64% improvement in terms of NC and CPU. The results of these two methods on the 26 cases of Problem 2 are given in Appendix 2, Tables 2-4-2 and 2-5-2 whereas the comparison results of these methods against the F.R and P.R methods are given in Appendix 3, Tables 3-4 and 3-5.

Surprisingly however, Hybrid 1 performed extremely well on this particular problem. In fact, apart from Hybrid 3 and when using the new restarting criteria, Hybrid 1 performed better than any other conjugate gradient method described in this thesis. Compared to the P.R method it achieved some 23%, 22%, 27% and 27% in terms of the NI, NF, NC and CPU respectively whereas when compared to the F.R method it achieved 64%, 63%, 66% and 63% in terms of the NI, NF, NC and CPU respectively. The results of this method on this problem are given in Appendix 2, Table 2-6-2 and the comparison results are given in Appendix 3, Table 3-6.

ATH1, ATH2 and ATH3 too were able to better the performances of both the F.R and P.R methods in terms of both the NC and CPU. They achieved some 17%, 20% and 20% improvements in terms of the NC respectively and 1%, 5% and 6% improvements in terms of cpu time respectively over the P.R method and 62%, 63% and 63% in terms of the NC and 50%, 52% and 53% improvements in terms of cpu time respectively over the F.R method. We note that on this particular problem, Problem 2, ATH2, ATH3, BTH, Hybrid 2 ($\tau = 10^{-4}$) and Hybrid 2 ($\tau = 10^{-6}$) gave identical results. BTH however, was the best in terms of cpu time as expected. Hybrid 2 ($\tau = 10^{-8}$) on the other hand, was 12% better than the P.R method in terms of the NC for no extra cpu time to speak of and was 60% better than the F.R method in terms of NC with half the cpu time needed by the F.R method. See the respective Tables for the individual and comparison results in Appendices 2 and 3. The results obtained by Hybrid 3 and by the use of the new restarting procedure were by far better than any other result of the other methods on

this particular problem. Hybrid 3 betters the P.R method by 70%, 66%, 71% and 74% in terms of the NI, NF, NC and cpu time respectively and better; the F.R method by 86%, 84%, 87% and 87% in terms of the NI, NF, NC and cpu time respectively. Also the new restarting procedure applied to the F.R and P.R methods achieved about the same percentages as Hybrid 3 on this problem. The results of these methods applied to Problem 2 are given in Appendix 2 and the comparison results in Appendix 3.

The Results Obtained for Problem 3 :

ORIG1 and Hybrid 1 have failed to better the performance of the Polak-Ribière method on this problem. In fact Hybrid 1 has again failed to better even the Fletcher-Reeves method. ORIG2 on the other hand, did perform better than both the F.R and the P.R method. It achieved 16%, 16%, 22% and 24% improvements over the Polak-Ribière method and 61%, 60%, 64% and 66% improvements over the Fletcher-Reeves method in terms of the NI, NF, NC and cpu time respectively. The results of these methods can be found in Appendices 2 and 3 in the respective Tables.

ATH1 and ATH2 were only slightly better than the P.R method whereas ATH3 showed a fairly considerable improvement. The improvements achieved by those three methods were some 3%, 1% and 10% improvements in terms of NC respectively at the expense of some 7.4%, 9% and 0% extra cpu time respectively over the P.R method. As to their performances against that of the F.R method they were 25%, 23% and 30% better in terms of the N.C respectively and 14%, 11% and 20% better in terms of cpu time respectively. The B.T.H. method on the other hand, achieved a 7% improvement in terms of the N.C and 5% improvement in terms of cpu time over the P.R method and 28% in terms of NC and 24% in terms of cpu time improvements over the F.R method.

As to Hybrid 2 with $\tau = 10^{-4}$, $\tau = 10^{-6}$ and $\tau = 10^{-8}$, it achieved'8%, 7% and 2% improvements over the P.R method in terms of N.C. for the three values of τ respectively at the expense of some 1%, 1% and 6.5% extra cpu time. Compared to the F.R method, Hybrid 2 for these respective values of the scalar τ , achieved 28%. 28% and 23% improvements in terms of the N.C and some 19%, 19% and 14% improvements in terms of the cpu time respectively. See the respective Tables in Appendices 2 and 3 for the explicit results of these method on Problem 3. Hybrid 3 performed as well as the P.R method on this problem in terms of NC and cpu time and achieved 3% improvement in terms of both NI and NF. Ϊt however, bettered the Fletcher-Reeves method by 26%. 22%, 22% and 19% in terms of NI, NF, NC and cpu time respectively. The results obtained by this method on this problem with its 26 cases are given in Appendix 2, Table 2-15-3 and those comparing the method to both the F.R and P.R methods are given in Appendix 3, Table 3-15. As to the new restarting procedure used with the F.R and P.R methods, it has in both cases been able to out-perform the straight-forward Fletcher-Reeves method, but failed in both cases to better the performance of the straight-forward Polak-Ribière method. Their results are given in Appendices 2 and 3.

The Results Obtained for Problem 4 :

On this particular problem, most of the hybrid methods have either failed to better the performance of the P.R method or only achieved a slight improvement. The only hybrid method that achieved a very good improvement was Hybrid 3. Also the new restarting procedure achieved excellent results on this problem. Let us look at these results in more detail. ORIG1 has achieved a 3% improvement in terms of the NC and 11% in terms of cpu time over the P.R method and 14% in terms of the NC and 11% in terms of cpu time over the F.R method. ORIG2 did slightly better than that by achieving 7% and 18% improvements in terms of the NC and 11% and 11% improvements in terms of cpu time over the P.R and F.R methods respectively. Hybrid 1 on the other hand, was again worse than the P.R method but was able to better the performance of the F.R method by 4% in terms of the NC for 7.4% extra cpu time. ATH1 was unable to beat the performance of the P.R method and was some 7% better than the F.R method in terms of the NC at the expense of some 23% extra cpu time. ATH2 and Hybrid 2 with $\tau = 10^{-8}$ were able to out-perform the method of P.R achieving 4% and 8% improvements respectively in terms of the NC at the expense of some 16% and 7.4% extra cpu time respectively. As to ATH3, BTH, Hybrid 2 ($\tau = 10^{-4}$) and Hybrid 2 ($\tau = 10^{-6}$) performed as well as the P.R method did on this particular problem and were 10% better than the F.R method in terms of the NC. The B.T.H method was the only method out of these latter methods that did not use any extra cpu time.

Hybrid 3 however, achieved some excellent results on this problem. Its measured improvement over the P.R method was represented by 68%, 66%, 74% and 75% gains in terms of the NI, NF, NC and cpu time respectively, whereas over the Fletcher-Reeves method it achieved some 73%, 71%, 77% and 75% improvements in terms of the NI, NF, NC and cpu time respectively. They are in fact the improvements achieved on this problem and on Problem 2 that made Hybrid 3 the best of the conjugate gradient methods discussed in this thesis. The new restarting procedure applied to the methods of F.R and P.R also produced results as excellent as those of Hybrid 3 on this particular problem.

The Results Obtained for Problem 5 :

On this problem, apart from Hybrid 3 and the P.R method with new restart which achieved some reasonable improvements over the method of P.R all the other hybrids had more or less about the same performance as those of the P.R method, the best of which was ORIG2 which achieved 4%, 3%, 2% and 6% improvements in terms of NI, NF, NC and cpu time respectively over the P.R method and 78%, 76%, 80% and 80% improvements in terms of the NI, NF, NC and cpu time respectively over the F.R method. Hybrid 3 however, achieved 9%, 8%, 9% and 9% improvements in terms of the NI, NF, NC and cpu time respectively over the P.R method and 79%, 77%, 81% and 81% improvements over the F.R method in terms of the NI, NF, NC and cpu time respectively. The new restarting procedure applied to the P.R method performed about as well as Hybrid 3, whereas when applied to the F.R method it failed to improve on the straight-

forward P.R method. The results are given in Appendices 2 and 3.

The Results Obtained for Problems 6 and 7 :

We put those two problems together for the reason that the P.R method has performed so well on these problems that no other method has been able to out-perform it. We therefore only refer to the results given in the Appendices 2 and 3 which are self explanatory.

Discussion of the Overall Results :

The overall performances of these Hybrid methods compared to those of the F.R and P.R methods were as follows:-

ORIG1 achieved some 49%, 46%, 49% and 52% improvements over the method of F.R in terms of NI, NF, NC and cpu time respectively and obtained some 4%, 4%, 6% and 12% improvements over the P.R method in terms of the NI, NF, NC and cpu time respectively. This shows that the idea of replacing the negative updates of the P.R method by F.R updates was a good one but still not as good as that of replacing them by zero as Powell suggested. The idea here however, was to attempt to adapt the method to allow a possibility of a global convergence proof. The use of the Hestenes and Stiefel update in the algorithm which resulted in the algorithm ORIG2 did improve the results a great deal but did not improve the method any further towards finding a global convergence proof. ORIG2 was some 10%, 10%, 12% and 15% better than the P.R method and some 52%, 50%, 52% and 53% better than the F.R method in terms of the NI, NF, NC and cpu time respectively. The idea used in Hybrid 1 however, had led us to find a global

convergence proof of the algorithm but was too restrictive in its choice of updates which resulted in a fairly poor computational result. In fact Hybrid 1 was the only method out of the new hybrids that failed to improve on the Polak-Ribière method. It was 23%, 21%, 20% and 21% worse than the Polak-Ribière and 30%, 29%, 32% and 30% better than the Fletcher-Reeves method in terms of the NI, NF, NC and cpu time respectively. The use of the angle test together with Hybrid 1 that resulted in the ATH method did improve the computational performance of the method but we were only able to prove the global convergence of the method with exact line searches. When inexact line searches are used the improvement achieved by ATH is not only at the expense of some extra cpu time but also at the expense of losing the global convergence that was achieved for Hybrid 1. However, it was necessary to follow this path of ideas to find the best possible hybrid in both theoretical and computational terms. ATH1 achieved 46%, 44%, 46% and 36% improvements over the F.R method in terms of the NI, NF, NC and cpu time respectively. Compared to the P.R method it achieved 2% improvement in terms of the index of computational labour but needed a few more iterations and function evaluations on top of some 14% extra cpu time. When $\tau = 0.01$, the ATH method only needed some 10% extra cpu time to achieve 3%. 3% and 7% improvements over the P.R method in terms of the NI, NF and NC respectively leading to the best value of τ for ATH. For $\tau = 10^{-6}$ ATH was only slightly worse than with $\tau = 10^{-4}$ achieving for some 10% extra cpu time some 3%, 4% and 6% improvements over the P.R method in terms of the NI, NF and NC respectively.

Over the F.R method it achieved 48%, 46%, 48% and 39% improvements in terms of NI, NF, NC and cpu time respectively.

The idea of using the beta test instead of the angle test was interesting for it achieved roughly the same results as did the best ATH but with much less cpu time. It, in fact, achieved 3%, 3%, 6% and 3% improvements over the P.R method and 48%, 46%, 48% and 47% improvements over the F.R method in terms of NI, NF, NC and cpu times respectively. Up to now the global convergence in the case of inexact line search that was achieved for Hybrid 1 had not yet been restored. This was however, again obtained by using the angle test and the beta test simultaneously which resulted in what we called Hybrid 2. For $\tau = 10^{-4}$ and $\tau = 10^{-6}$ roughly the same results were obtained, improving the P.R method by 3%, 3% and 4% respectively, and 5% at the expense of some 9% extra cpu time, in terms of NI, NF and NC respectively and improving the F.R method by 48%, 46%, 48% and 40% in terms of NI, NF, NC and cpu time respectively. For $\tau = 10^{-8}$ better overall results were obtained improving on the P.R method by 3%, 3%, 7% at the expense of some 7% extra cpu time in terms of NI, NF and NC and improving on the F.R method by 48%, 46%, 49% and 41% in terms of NI, NF, NC and cpu time respectively. Although ORIG2 had obtained better results than Hybrid 2 with $\tau = 10^{-8}$, Hybrid 2 has the advantage over ORIG2 that it ensures a descent property to hold on each iteration and achieves global convergence whereas ORIG2 does not. Also ATH2 performed as well as Hybrid 2 with $\tau = 10^{-8}$ but not only is Hybrid 2 globally convergent even when inexact line searches are used but it also achieves its improvements

in less cpu time than ATH2. This therefore makes Hybrid 2 with $\tau = 10^{-8}$ our best Hybrid method so far.

The modification of condition (4.3.6) in Chapter 4 and its replacement by condition 5.2.1 of Chapter 5, and the use of condition (5.2.5) of Chapter 5 instead of condition (4.3.10) of Chapter 4 in the algorithm that resulted in Hybrid 3 algorithm turned out to be the best idea theoretically and computationally. Indeed not only did we obtain an algorithm that ensures a descent property to hold on every iteration and that is globally convergent, for both cases when exact or inexact line searches are used throughout the algorithm, but one that also achieves excellent improvement over both the F.R and the P.R methods computationally. Hybrid 3 uses two scalars λ and μ . Although different values of these scalars work better in different types of problems, Hybrid 3 achieves its best overall results when $\lambda = 10^{-8}$ and $\mu = 0.1$. It betters the F.R method by 75%, 71%, 76% and 75% and betters the P.R method by 53%, 48%, 56% and 55% in terms of NI, NF, NC and cpu time respectively. Good results were also obtained by using the new restarting procedure with the F.R and P.R methods. The F.R method with new restart bettered the straight-forward method of F.R by 72%, 68%, 73% and 72% and bettered the P.R method by 47%, 43%, 50% and 49% in terms of NI, NF, NC and cpu time respectively whereas the P.R method with new restart bettered the straight-forward P.R method by 55%, 49%, 56% and 52% and bettered the F.R method by 76%, 72%, 76% and 74% in terms of NI, NF, NC and cpu time respectively. Hybrid 3 is therfore the best of all the conjugate gradient methods described herein not only because

it achieves the same results as the P.R method with new restart for slightly less cpu time but also because the P.R method with new restart can only be shown to be globally convergent if its update does not at any stage become negative which is obviously not always true.

3. COMPARISON OF HYBRID 3 WITH A QUASI-NEWTON METHOD.

Quasi-Newton methods have always been considered to be far more successful than conjugate gradient methods in numerical computations. Their drawback however, is their need to store an n×n matrix at every iteration to approximate the Hessian of the objective function. This restricts the application of the method to only medium size problems. Because of the considerable improvement of conjugate gradient methods achieved by Hybrid 3 in this thesis, it is felt that it is worthwhile comparing the performance of Hybrid 3 to that of a quasi-Newton method on the test problems considered in this thesis. We used the N.A.G. routine EØ4KBF which contains the code for the quasi-Newton method as described by Gill and Murray (1972). First, an attempt was made to solve all the 182 cases resulting from the seven extended test problems considered in this thesis, but it was found that for some problems such as Problem 2 (Wood), the method failed to solve cases of higher than 160 variables because of the considerable amount of cpu time needed. To solve the Wood test problem with 160 variables, EØ4KBF needed over 6 hours of cpu time which is incredibly high, whereas the Fletcher-Reeves method only needed about 18.4 seconds of cpu time. Therefore, it was

decided to compare the results of the methods considering the seven test problems with up to 160 variables. In Appendix 3, Tables 3-18, 3-19, 3-20 and 3-21 show the summarized results of the F.R, P.R, Q.N and Hybrid 3 methods respectively. These tables also contain the ratios comparing the methods to each other with the problems considered with up to 160 variables. First we note that the Quasi-Newton methods may need more iterations than a conjugate gradient method but at the same time improve a great deal the index of computational labour. This feature is clearly illustrated in Table 3-20, Problem 6 for example. The Q.N method was 40% worse than the P.R method in terms of numbers of iterations but improved the index of computational labour by 55%. As to its comparison with Hybrid 3, Hybrid 3 managed to better the Q.N method overall by 66%, 77%, 33% and 99.3% in terms of NI, NF, NC and CPU respectively.

We also note that the Q.N method had failed to better the P.R method overall (see Table 3-20) and therefore we feel that the situation with the considered test problems is not too realistic and it is therfore only expected that Hybrid 3 would out-perform the Q.N method since Hybrid 3 already out-performs the P.R method. However, we note that the Q.N method has performed rather poorly on Problem 1 and therefore we constructed a new set of results considering only problems 2 to 7. These results that are given in Table 3-22, Appendix 3, do reflect the usual situation where the P.R method out-performs the F.R, the Q.N method out-performs the P.R method and more important, Hybrid 3 still out-performs the Q.N. method.

By considering the test problems for medium size, i.e. up to 160 variables, we draw out another interesting feature of Hybrid 3 by comparing its improvements over the P.R method for the up to 500 variable problems with those for the up to 160 variable problems. The improvements achieved for the former are greater than those achieved for the latter. Consequently we can conclude by saying that Hybrid 3 works even better when the number of variables increases, i.e. for high dimensional problems. This is a very useful aspect of the method.

Appendix 1

Proofs of Theorems Given

in Chapter 2.

1. PROOF OF THEOREM 2.2.1.

<u>Part 1</u>: Let x^* be an optimal solution of the problem (2.2.4) and suppose that there exists $s \in Z(x^*)$ such that $s^T \nabla f(x^*) < 0$. This means that f can further be reduced in the feasible direction s. In other words, this means that there exists $\tau > 0$ such that:

 $f(x^*) > f(x^* + \alpha s)$ for $0 < \alpha \leq \tau$.

But s is in $Z(x^*)$, which implies that there exists $\overline{\alpha}$ such that:

$$x^* + \alpha s \in K \qquad \text{for } 0 \leq \alpha \leq \overline{\alpha}.$$

Finally, if we take α such that $0 < \alpha \leq \min\{\tau, \overline{\alpha}\}$, we obtain:

 $f(x^*) > f(x^* + \alpha s)$ and $x^* + \alpha s \in K$

which contradicts the fact that x^* is an optimal solution of (2.2.4) and hence the proof of the first part of the theorem is complete.

<u>Part 2:</u> To prove the second part of the theorem, we only need to show that

 $s^{T} \nabla f(x^{*}) \ge 0 \quad \forall s \in \overline{Z(x^{*})} \Rightarrow x^{*} \text{ is optimal,}$

since the inverse implication is already shown in the first part of the proof above.

The assumption that g_1, \ldots, g_m are quasi-convex implies that

the set K of admissible points is a convex set (This is a

convexity result). Therefore if $x \in K$ we obtain:

$$\alpha x + (1-\alpha)x^* = x^* + \alpha(x-x^*) \in K$$
 for all $\alpha : 0 \leq \alpha \leq 1$.

So, if we take $s = x - x^*$, we have $s \in Z(x^*)$ which by hypothesis means that:

$$(x-x^*)^T \nabla f(x^*) \ge 0.$$

But f is pseudo-convex; therefore, by definition of a pseudoconvex function we obtain:

$$(x-x^*)^T \nabla f(x^*) \ge 0 \Rightarrow f(x) \ge f(x^*)$$

which completes the proof of the second and last part of the theorem.

2. PROOF OF THEOREM 2.5.2.

$$x \in Z \implies x = x^{(1)} + z \text{ where } z \in [z^{(1)}, \dots, z^{(n)}]$$
$$\implies x = x^{(1)} + \sum_{i=1}^{m} \alpha_i z^{(i)} \text{ where } m \leq n$$
$$\implies f(x) = f(x^{(1)} + \sum_{i=1}^{m} \alpha_i z^{(i)}) .$$

By definition of the quadratic function f, this implies that:

$$f(x) = a + b^{T} \left(x^{(1)} + \sum_{i=1}^{m} \alpha_{i} z^{(i)} \right) + \frac{1}{2} \left(x^{(1)} + \sum_{i=1}^{m} \alpha_{i} z^{(i)} \right)^{T} C \left(x^{(1)} + \sum_{i=1}^{m} \alpha_{i} z^{(i)} \right)$$
$$= a + b^{T} x^{(1)} + \frac{1}{2} x^{(1)^{T}} C x^{(1)} + \sum_{i=1}^{m} \left[\alpha_{i} z^{(i)} (C x^{(1)} + b) + \frac{1}{2} \alpha_{i}^{2} z^{(i)^{T}} C z^{(i)} \right]$$
$$= f(x^{(1)}) + \sum_{i=1}^{m} \left[\alpha_{i} z^{(i)^{T}} \nabla f(x^{(1)}) + \frac{1}{2} \alpha_{i}^{2} z^{(i)^{T}} C z^{(i)} \right] \qquad (*)$$

Similarly we have:

$$f(x^{(i)} + \alpha_i z^{(i)}) = f(x^{(i)}) + \alpha_i z^{(i)^{T}} (Cx^{(i)} + b) + \frac{1}{2} \alpha_i^2 z^{(i)^{T}} Cz^{(i)}$$

Since
$$z^{(i)} C(x^{(i)} - x^{(1)}) = 0$$
, then $z^{(i)} Cx^{(i)} = z^{(i)} Cx^{(1)}$;

and therefore:

٠

$$f(x^{(i)} + \alpha_i z^{(i)}) = f(x^{(i)}) + \alpha_i z^{(i)^T} \nabla f(x^{(1)}) + \frac{1}{2} \alpha_i^2 z^{(i)^T} C z^{(i)}$$
(**)

Because of equation (**), equation (*) becomes

$$f(x) = f(x^{(1)}) + \sum_{i=1}^{m} \left[f(x^{(i)} + \alpha_i z^{(i)}) - f(x^{(i)}) \right]$$

$$\geq f(x^{(1)}) + \sum_{i=1}^{m} \left[f(x^{(i)} + \alpha_i^* z^{(i)}) - f(x^{(i)}) \right] = f(x^*)$$

and thus the proof is complete.

Appendix 2

Explicit Sets of Results

This appendix contains the tables of the explicit extensive sets of results. Testing any conjugate gradient method on any of the test problems considered in this thesis involves running the corresponding version of the program 26 times, each run producing a set of results containing the number of variables (NV), the number of iterations (NI), the number of function evaluations (NF), the index of computational labour (NC), the cpu time needed to reach the minimum (CPU) and the function value at the minimum (FV). These extensive sets of results are presented in the tables of this appendix as follows: Tables 2-i-j contains the results of the 26 runs of method i (i = 1, ..., 17) on the test problem j (j = 1, ..., 7). It also contains the totals of the 26 runs in the bottom row. In the case of the Quasi-Newton method, the testing of the method on any of the test problems considered in this thesis only involves running the program 9 times (up to 160 variables). The sets of results produced by this method have the same format as those of the conjugate gradient methods. The notation used in this appendix and the next one is as follows:

NV	:	Number	o£	Variables.

NI : Number of Iterations.

NF : Number of Function Evaluations.

NC : Index of Computational Labour.

CPU : Cpu time.

FV : The Function Value Obtained On Convergence.

190

NNNNNNN

The figures representing the Cpu time are to the 6^{th} decimal of a second. For example the number 156324192 should be read 156.3 seconds or 2 mins. 36.3 secs.

Appendix 3

Summarized and Comparison Results

This appendix contains the tables of the summarized results and the comparison of the new methods with the existing ones. Tables (3-i) i = 1,2,...,17 contain the totals from the bottom rows of Tables (2-i-j) i = 1,...,17, j = 1,...,7 of Appendix 2, followed by the ratios of these totals for the particular method over those of the Fletcher-Reeves method and over those of the Polak-Ribière method. Table (3-18) contains the totals for the F.R method on problems up to 160 variables. Table (3-19) shows the same totals for the P.R method, followed by the ratios comparing the P.R method to the F.R method. Table (3-20) contains the bottom rows of Tables (2-i-j) i = 18 and j = 1,...,7 from Appendix 2, followed by the ratios comparing the Q.N method with both the F.R and the P.R methods. Table (3-21) shows the totals for Hybrid 3 on problems up to 160 variables, followed by the ratios comparing Hybrid 3 to the F.R, the P.R and the Q.N methods. Finally Table (3-22) shows the results obtained by not considering the Rosenbrock test problem. The same notation is used as in Appendix 2.
