Abstract

Fuel economy is a growing concern for both manufacturers within the automotive sector and consumers. Increasing government legislation is driving towards greener vehicles with reduced CO_2 and NOx emissions and greater fuel economy, especially within urban environments. Manufacturers use new technologies in their powertrain systems to tackle these problems. This paper simulates and evaluates the performance of using a half toroidal CVT in series with a conventional multi-speed transmission, by analysing different shifting strategies to optimise fuel consumption and NOx emissions over the NEDC using this novel approach. The results show an 8.83% increase in fuel economy and up to an 11.34% reduction in NOx emissions is possible using this arrangement. The introduction of CVT adds a further 1.18% increase in fuel economy and 3.59% decrease in NOx emissions. The paper concludes that this novel arrangement should be considered by automotive manufacturers as a solution for improvements to powertrain technology.

Keywords

Toroidal CVT, Optimum Gear Ratio, Fuel consumption, Nitrogen Oxide Emissions, New European Driving Cycle

1. Introduction

In 2013 the transport sector was accountable for approximately 26% of greenhouse gases emitted in the UK [1]. The UK government has targeted consumers with financial incentives to purchase new cars emitting less than 95 grams CO_2 /km by introducing a Vehicle Excise Duty (VED), which entitles vehicles that emit less than 95 grams CO_2 /km an exemption from the levy, aiming to reduce overall CO_2 emissions

by 34%. A study by Holmberg et al. [2] found that approximately 33% of fuel used in passenger vehicles is used to overcome mechanical friction, which for a 2010 passenger car equates to roughly 340 litres of fuel per annum.

Many strategies have been used to optimise the fuel efficiency of Internal Combustion Engines (ICEs) and powertrain systems. Technology such as fuel direct injection (DI), has been developed to improve overall fuel economy in ICEs by up to 20% [3], where the fuel is injected straight into the combustion chamber. Modern automotive manufacturers often turn to engine downsizing to improve fuel economy, whereby a turbo or supercharger is often used to increase the Indicated Mean Effective Pressure (IMEP) while reducing the engine capacity. Downsizing was not only proven to decrease fuel consumption over the NEDC cycle but also improve emissions [4, 5].

Variable compression ratios combined with variable valve actuation technology have also been shown to reduce fuel consumption by up to 13% over various drive cycles including the NEDC [6]. Cylinder Deactivation (CDA) and Stop/start have also been used by manufacturers to improve fuel consumption [7, 8].

A possible method to reduce CO_2 emissions of a Rear Wheel Drive (RWD) vehicle is to add a Continuously Variable Transmission (CVT) in series with a conventional 5 speed gearbox. A CVT is a device that allows the ratio of the speeds of the driven shaft and the driving shaft to be altered, within a range governed by its physical geometry, infinitely. The implementation of a single cavity half toroidal CVT could allow the engine to operate in the most fuel-efficient or reduced NOx emission regions for longer because of the continuous transmission ratios that it permits opposed to discrete. Moreover, a clutch mechanism could be used to bypass the CVT and only use the 5-speed transmission, when the internal power loss of the CVT compromises the improvement of fuel consumption or reduced NOx emissions.

Research into geometrical optimisation of a toroidal CVT has shown greater efficiencies are achieved when the Elastohydrodynamic Lubrication (EHL) oil temperatures and rotational velocities of the input disk are both low [9]. When designing a toroidal CVT rolling fatigue life and maximum contact stress on the roller surfaces and disks must be considered [10]. Moreover, full and half toroidal CVTs

have been compared, finding the latter has an efficiency advantage over full toroidal CVTs, because the spin losses are less [11]. When the CVT is in use, there is an EHL rolling contact between the disk and the roller, inducing boundary and viscous friction due to the thin lubricant film. Power loss is induced within the contact, decreasing the overall efficiency of the torque transmission.

This paper investigates a CVT in series with a 5-speed gearbox. A system level model of a vehicle was developed to investigate gear shifting strategies and optimisation of gear ratios. The model simulated fuel consumption and NOx emissions over any given speed trace. A component level model of a single cavity half toroidal CVT is developed. The component level model is used to predict several parameters including boundary and viscous friction calculating the power loss due to spin. The maximum sub-surface shear yield stress, calculated from pressure within the contact, has been used as a limiting factor as to whether the use of the CVT will cause excessive surface wear and pitting of the cavity and roller. The simulation calculates the optimal gear ratios of a half toroidal single cavity CVT in series with a 5-speed gear box, further improving fuel economy and reducing NOx emissions.

2. System Level Model

The system level model describes the kinematic model of the transmission ratio of a 5 or 6-speed gearbox, and the optimisation of individual gear ratios. A separate calculation is required for the first gear ratio as it has set criteria to achieve such as hill starts. In addition to this, the top gear ratio will be selected with consideration of the legal maximum road speeds in the UK. All emission tests to date require a speed trace to be followed by a driver. There is a slight allowance for deviations from the target speeds; however, this simulation will follow the speed trace exactly. This is because the torque required of the engine will be back calculated from the velocity of the wheel. The simulation also considers CVT in series with the transmission.

2.1 Half Toroidal CVT:

The basic functionality of a toroidal CVT is as follows: an input disk has the angular velocity equivalent to that of the engine speed. The input disk is in contact with multiple rollers, which are used to transmit torque to the output disk. The rollers

change the angle at which it lies between the input and output disk, either increasing or decreasing the speed of the output disk. The lubrication in the disk – roller conjunction is paramount to its efficient operation. A very high load is required for the rollers to transmit torque from one disk to another. resulting in the formation of an EHL film. The toroidal CVT allows for greater performance in terms of driveability and comfort for passengers in comparison to 5-speed transmissions, which greatly benefits urban driving environments where there is greater transients. A kinematic model is used to describe the transmission ratio of the CVT, requiring material selection for the disks and rollers to allow for sufficient durability of the system. The system geometry is defined in Figure 1 and 2, and the parameter inputs used in the simulation are displayed in Table 1.

CVT Transmission Ratio:

The transmission ratio of the CVT is assumed to be ideal for the preliminary simulation, where the ideal ratio is calculated using:

$$i = \frac{R_3}{R_1} = \frac{e - \cos(q - f)}{e - \sin(\phi)} \tag{1}$$

Where ϕ is the possible angle and e is the minimum radius of the disk.

In reality, creep occurs when there is a velocity difference $(V_1 - V_2)$ between the roller and disk (1), and thus must be taken into consideration;

$$cr_{in} = \frac{V_1 - V_2}{V_1} = \frac{\omega_1 R_1 - \omega_2 R_{22}}{\omega_1 R_1} \tag{2}$$

Where ω_1 is the angular velocity, R_1 is the input radius and R_{22} the radius of the roller.

Table 1: Geometry Used in Simulation

Parameter Symbol	Unit	Definition	Parameter Symbol	Unit	Definition
R_1	m	Input Radius	R_{12}	-0.040m	Radius of the Cavity
R_3	m	Output Radius	R_{21}	0.0202m	Roller Curvature
q	Rads	Half Cone Angle of the Roller	R_{22}	0.032m	Radius of the Roller
f	Rads	Roller Tilt Angle	e	0.025m	Minimum distance from toroidal centre to cavity edge

5

Material Selection for CVT:

 The criterion for the material for the CVT's roller and disk are like that of a bearing [10], such that it should be; high hardness, good wear resistance, high rolling fatigue strength, operation temperature should be up to 200ºC, smooth surface finish and corrosion resistant. Therefore, AISI 52100 Steel has been chosen with material composition shown in Table 2 and thermal properties in Table 3.

Table 2: AISI 52100 Composition

SAE 52100 Composition						
C	Si	Mn	Cr	P	S	Application
0.98-1.1%	0.15-0.30%	0.25-0.45%	1.3-1.6%	0.025%	0.025%	Bearings typically

Table 3: Mechanical Properties of AISI 52100

SAE 52100 Mechanical Properties						
Density	Specific Heat	Thermal Conductivity	Young's Modulus	Yield Strength	Poisson's Ratio	Hardness (Rockwell)
g/cm^3	kJ/kg.k	W/m.K	MPa	MPa		HRC
7.83	0.46	43	201	1410	0.28	62 [14]

Rear Wheel Drive Transmission: The model utilises a rear wheel drive transmission. A rear wheel drive model has enough space between the transmission and the differential. The CVT could be an additional unit installed in front of the main transmission with a clutch pack in front. If the half-toroidal CVT was packaged in a compact manner, it could be placed with the transmission tunnel itself. For a standard RWD transmission layout, the torque of the engine is transmitted via a clutch to the input shaft. However, in the simulation the torque from the engine is transmitted via an engaged clutch to the CVT. The output disk will then transmit the torque to an input shaft of a fixed gear ratio, thus transferring torque to a lay-shaft. The lay-shaft in turn drives different pairs of gears dependent on which gear is selected. The output from the final gear passes the torque to the driveshaft, which transfers the torque to a differential. The torque is multiplied by the ring gear and transferred to the back two wheels [15].

The rotational speed of the rear wheels and torque are:
$$T_w = \varphi_{Input}\varphi_{CVT}\varphi_{Gear}\varphi_{Diff}T_{Eng} \tag{3}$$

$$N_w = \frac{N_{Eng}}{\varphi_{Input}\varphi_{Gear}\varphi_{Diff}R_{CVT}} \tag{4}$$

To simplify the simulation the overall gear ratios will be calculated instead of the individual gear ratios.

$$T_w = T_{Eng}\varphi_{CVT}\varphi_n\eta \tag{5}$$

$$N_w = \frac{N_{Eng}}{\varphi_n\varphi_{CVT}} \tag{6}$$

2.2 Vehicle Longitudinal Dynamics:

Equation 7 is used to simulate the vehicle's longitudinal dynamics [16]:
$$\sum F = M_v a = F_x - (F_D + F_R + F_G) \tag{7}$$
where, F_x is the tractive force, F_D aerodynamic drag, F_R the resistance to rolling and F_G is any loading due to a gradient of the road. This is also shown in Figure 3.

The traction force is to include the drivetrain inertias. If drivetrain inertias were not considered, there would be an underestimation of the fuel consumption and the amount of NOx emitted [16]:

$$F_x = \frac{T_{Eng}R_{CVT}R_n\eta}{r_w} - \frac{a}{r_w^2}I_{Eff} \tag{8}$$
Figure 3: Free Body Diagram of Rear Wheel Drive Vehicle

The inertia stated in equation 8 is calculated via:

$$I_{Eff} = (I_E + I_{F,C} + I_{T,in})(\varphi_{in}\varphi_n\varphi_{F.D})^2 + I_{T,\text{lay}}(R_n R_{F.D})^2 + (I_{T,\text{out}} + I_P)\varphi_{F.D}^2 + I_D + I_S + I_W \tag{9}$$

The aerodynamic drag, rolling resistance, and coefficient of friction considered are [16]:

$$F_D = \frac{1}{2} c_D \rho A_f v^2 \tag{10}$$

$$F_R = \mu M_v g \cos \theta_{road} \tag{11}$$

$$\mu = 0.01 \left(1 + \frac{2.23694v}{147}\right) \theta_{road} > 0 : \text{uphill gradient} \tag{12}$$

The loading due to the gradient of the road is:

$$F_G = M_v g \sin \theta_{road} \tag{13}$$

However, during chassis dynamometer tests there are no gradient compensations considered and so $F_G = 0$ in that case.

2.3 Gear Ratio Selection Considerations:

First gear must have a high enough torque transmission to guarantee the vehicle's hill start from at least a 33% gradient [17]. In first gear a creep speed is expected to negate unwarranted clutch usage in congested driving scenarios [18]. When considering Equation 13, as the gradient increases positively, the force required to overcome the loading, due to gradient of the road, increases.

Top gear selection targets optimal fuel consumption and NOx emissions rather than the achieving greater maximum speeds. For legal UK motorway speed limits, the top vehicle speed is 70 mph, which has been factored into calculation of the top gear ratio. The BSFC map of the engine selected shows the best fuel economy figures will be achieved near full load between 2000 and 3000 rpm.

2.4 Gear Shifting Strategy:

The shifting strategy focuses on either best fuel economy or NOx emissions. A series of nested loops are utilised to find the impact of changing an individual gear ratio and ultimately achieve the optimised solution for the transmission system. This strategy also incorporates a set limit for the engine speed to remain within idle and max engine speed. The torque curve of the vehicle is used to define the maximum torque limit at any given engine speed, assuming that during the drive cycle the transmission would follow a strategy to minimise either NOx or fuel consumption.

2.5 Component Level Model:

The component level model of the CVT predicts the power loss at a specified torque and engine speed to only use the CVT when it is beneficial to the fuel economy. Moreover, the model accounts for the durability of the CVT. The contact between the disks and the rollers cause power loss due to the generation of boundary and viscous friction, limiting the durability of the component. The sub-surface stresses could surpass their elastic limit if the strategy employed for the components is

incorrect. The maximum surface shear stress criterion is used to ensure the durability of the CVT, where $\tau_{max} = 0.30p_0 \geq 0.5\sigma_Y$ [19]. In order to avoid the CVT in use near the yielding point a safety factor of 1.2 has been utilised in the simulation [20].

Viscous Friction:

Evans and Johnson [21] produced friction maps of different lubricant types, accounting for thermal and elastic effects in the lubricant film. The elastic effect of the lubricant is governed by the fluid's shear modulus as well as the elastic compliance of the surfaces. CVT lubricant traction is governed by the regime where non-linear viscosity is experienced. The maximum coefficient of friction is calculated as [22]:

$$\mu_m = 0.87\,\bar{\alpha}\bar{\tau}_0 + 1.74\frac{\bar{\tau}_0}{\bar{p}}\,ln\left\{\left\{\frac{1.2}{\bar{\tau}_0 h_0}\left(\frac{2k\eta_0}{1+9.6\xi}\right)\right\}\right\}^{1/2} \tag{14}$$

ξ is a non-dimensional parameter:

$$\xi = \frac{k}{h_0}\left(\frac{16\bar{p}R\prime}{\pi E\prime k\prime \rho\prime c\prime U}\right)^{1/2} \tag{15}$$

To calculate the viscous friction the normal load is multiplied by the maximum coefficient of friction:

$$F_v = W \times \mu_m \tag{16}$$

Boundary friction:

A model created by Greenwood and Tripp [23] assumed a Gaussian height distribution of asperities over a rough surface, indicating the deformation mode, and the shape of the asperities can be neglected with respects to the loading of the surfaces in contact. The total friction within the conjunction is calculated is obtained as a result of the boundary and viscous shear components:

$$f = f_v + f_b \tag{17}$$

The load share carried by the asperities due to boundary friction, f_b is:

$$f_b = \tau_0 A_a + \varsigma W_a \tag{18}$$

The eyring shear stress, τ_0, is obtained using viscometry or an Atomic Force Microscope in wet Lateral Force Microscopy mode [24]. The asperity load and contact area, W_a and A_a respectively, are obtained as:

$$W_a = \frac{16\sqrt{2}}{15}\pi(\zeta\kappa\sigma)^2\sqrt{\frac{\sigma}{\kappa}}E'AF_{5/2}(\lambda) \tag{19}$$

$$A_a = \pi^2 (\zeta \kappa \sigma)^2 \sqrt{\frac{\sigma}{\kappa}} A F_2(\lambda) \tag{20}$$

The Gaussian distribution below is used to describe the interaction probability of the asperities. The roughness parameter is assumed to be $(\xi \beta \sigma) = 0.055$, which is within the normal range for a steel surface [23, 25, 26]. The Gaussian Distribution leads to below statistical functions which are used to calculate the asperity contact area and load [18, 19]:

$$F_{5/2}(\lambda) = \begin{cases} -0.004\lambda^5 + 0.057\lambda^4 - 0.296\lambda^3 + 0.784\lambda^2 - 1.078\lambda + 0.617 \; ; for \; \lambda \leq 3 \\ 0 \hspace{8cm} ; for \; \lambda > 3 \end{cases}$$
$$\tag{21}$$

$$F_2(\lambda) = \begin{cases} -0.002\lambda^5 + 0.028\lambda^4 - 0.173\lambda^3 + 0.526\lambda^2 - 0.804\lambda + 0.500 \; ; for \; \lambda \leq 3 \\ 0 \hspace{8cm} ; for \; \lambda > 3 \end{cases}$$
$$\tag{22}$$

Film thickness:

Chittenden and Dowson produced and correlated theoretical expressions against experimental data in order verify and model the thickness of an EHL film in contact [27, 28]:

$$h_0 = 4.31 U_e^{0.68} G_e^{0.49} W_e^{-0.073} \left\{ 1 - e^{-1.23\left(\frac{R_s}{R_e}\right)^{2/3}} \right\} * R_e \tag{23}$$

R_s is the effective radius of curvature with respect to the direction of side leakage.

$$\frac{1}{R_s} = \frac{\sin^2 \theta}{R_x} + \frac{\cos^2 \theta}{R_y} \tag{24}$$

R_e is the effective radius of curvature regarding the direction of lubricant entrainment.

$$\frac{1}{R_e} = \frac{\cos^2 \theta}{R_x} + \frac{\sin^2 \theta}{R_y} \tag{25}$$

The dimensionless parameters used are G_e, U_e and W_e:

$$G_e = \frac{2}{\pi}(E'\alpha) \tag{26}$$

$$U_e = \frac{\pi \eta_0 V}{4E'R_e} \tag{27}$$

$$W_e = \frac{\pi W}{2E'R_e^2} \tag{28}$$

Spin and Powerloss Model:

The elliptical footprint of the contact between the roller and disk surface must be dimensioned in order to calculate the power loss due to spin. The major and minor axis of the ellipse can be found using [29]:

$$a_e = \left(\frac{6\bar{k}^2\bar{\varepsilon}WR\prime}{\pi\bar{k}Er}\right)^{1/3} \qquad (28)$$

$$b = \left(\frac{6\bar{\varepsilon}WR\prime}{\pi\bar{k}Er}\right)^{1/3} \qquad (30)$$

The maximum contact pressure within the ellipse is:

$$P_{max} = \frac{3W}{2\pi a_e b} \qquad (31)$$

The mean contact pressures for points in the ellipse are:

$$\bar{p} = \frac{W}{\pi a_e b} \qquad (32)$$

The ellipticity parameter is defined by:

$$\bar{k} = 1.0339\left(\frac{R_x}{R_y}\right)^{0.636} \qquad (33)$$

Brewe and Hamrock produced a numerical approximation to the simplified elliptical integral of the second kind [30]:

$$\bar{\varepsilon} = 1.0003 + \frac{0.5968R_x}{R_y} \qquad (34)$$

A [100x100] matrix (using polar coordinates) is used to calculate the 'radius' vector, to represent the ellipse, which are then multiplied by the angular spin velocity [31].

$$\omega_{spin} = (\omega_{disk}\sin(f)) - (\omega_{roller}\cos(q)) \qquad (35)$$

$$dV = r(i,j) * \omega_{spin} \qquad (36)$$

As the varying velocity vectors are now known the shear stress of each given point within the ellipse footprint can be computed:

$$\tau(i,j) = \frac{\eta_0 dV}{h_0} \qquad (37)$$

$$F_{vcell} = \tau(i,j)A_{cell} \qquad (38)$$

The power loss due to boundary and viscous friction can then be quantified by the following equation:

$$P(i,j) = \sum_i \sum_j (F_{vcell}(i,j) * dV(i,j)) \qquad (39)$$

3. Simulation Methodology

3.1 System Level Methodology

The model was developed in the program Matlab 2015b. The simulation overview is described in Figure 4.

Figure 4: Simplified Flow Chart of System Level Model

3.2 Component Level Methodology

The component level simulation is described in Figure 5.

4. Vehicle and Engine Data

The simulation uses vehicle data based on a C-segment 1.6L 4-cylinder petrol passenger vehicle [7]; however, for the current simulation the vehicle has been changed to rear wheel drive with a CVT in series with a 5 and 6 speed transmission.

Table 4: Original Simulation Vehicle Specification [7]

Original Vehicle Specification [7]	
Mass	1330 *kg*

Volume	1.5968 m^3
Engine Speed Max	7000 rpm
Engine Idle Speed	800 rpm
Engine Inertia	0.1224 kg.m^2
Cylinders	4

Table 6: Original Transmission Specification [7]

Original Transmission Specification [7]	
Type	5 Speed
Gear No.	Overall Gear Ratio
1st	14.5183
2nd	7.8892
3rd	5.4418
4th	3.9548
5th	3.2578

Half Toroidal CVT Specification	
Mass	100 kg
Speed Ratio	0.61-0.93
Number of Roller	3

To implement the CVT into the simulation additional mass had to be added to the kerb weight. An appropriate value of 100kg was chosen based on [32]. 3 rollers were selected over just two, because this would help to distribute some of the load required to transmit the torque and improve the durability of the CVT. The BSFC and NOx emission maps are taken from Douglas et al [7]. The specific point on the BSFC and NOx maps at which the engine is operating at, is then multiplied by the instantaneous power [33].

Converting units from g/kWh to g/s allows the instantaneous fuel consumption and the NOx emissions to be calculated:

$$\dot{m}_{fuel} = BSFC \times P_{Eng} = \frac{BSFC \times \left(\frac{2\pi}{60}\right) N_{Eng} T_{Eng}}{3.6 \times 10^6} \tag{40}$$

$$\dot{m}_{NOx} = NOX \times P_{Eng} = \frac{NOX \times \left(\frac{2\pi}{60}\right) N_{Eng} T_{Eng}}{3.6 \times 10^6} \tag{41}$$

To correlate the simulation closer to experimental NEDC results of Douglas et al the assumptions in Equations 42 and 43 were made due to the engine cold start significantly changing the fuel consumption values, but not the NOx emissions:

$$0 < t < 80\ (s) \quad \dot{m}_{fuel,cold} = 4 \times \dot{m}_{fuel,hot} \tag{42}$$

$$80 < t < 230\ (s) \quad \dot{m}_{fuel,cold} = 1.4 \times \dot{m}_{fuel,hot} \tag{43}$$

5. Results

The presented shifting strategy employed by Oglieve et al. [12] to validate the model against the NEDC model was to shift at a fixed engine speed of 2450 rpm using the original transmission and a 5-speed gearbox. The two shifting strategies applied in current simulations examine, for each given time step, all combinations of gear and CVT speed ratios as well as bypassing the CVT straight to the 5 speed gearbox via a clutch mechanism. The stored combinations that fulfil the criteria are then analysed

to find the optimum solution with either minimum BSFC or NOx engine out emissions.

5.1 Optimising 5-speed and 6-speed transmissions

The original 5 speed gearbox in [12] was used as a baseline to compare what improvement other systems could gain in fuel economy and NOx emissions. The shifting strategy was to minimise the fuel consumption, this was done by calculating the fuel consumption for each gear and selecting the gear with the lowest fuel but within engine torque and speed constraints such as redline and keeping above a minimum engine speed. By optimising the 5- and 6-speed gearbox in tandem with using the new minimum fuel shifting strategy a significant increase in fuel economy is gained as -7.02% and -7.65% respectively as shown in Table 8 and 9. The NOx emission reductions achieved by 5 and 6-speed gearboxes were both significant in comparison to the original shifting strategy with a 6.92 % and 7.75 % reduction respectively.

Table 8: Original and optimised transmission: shifting strategies and gear ratios [12]

Transmission	Shifting Strategy	Final Gear Ratio					
		1st	2nd	3rd	4th	5th	6th
Original 5 speed	Fixed	14.518	7.889	5.442	3.955	3.258	NA

Table 9: Results from original and optimised transmission [12]

Transmission	Shifting Strategy	Fuel Consumption	Fuel Reduction	NOx Emission	NOx Reduction
		g	%	g	%
Original 5 Speed	Fixed	641.19	NA	29.33	NA
Optimised 5 speed	Min Fuel	596.16	-7.02	27.44	-6.46
	Min NOx	617.90	-3.63	27.30	-6.92
Optimised 6 speed	Min Fuel	592.13	-7.65	27.32	-6.85
	Min NOx	610.56	-4.78	27.06	-7.75

5.2 CVT with a 5-speed and 6-speed transmissions

In this section the optimised gear ratios of the 5 and 6 speed gearboxes together with a CVT implemented in series is obtained. The use of the CVT with the 5 and 6-speed gearbox showed some improvement in fuel consumption as shown in Table 10. However, the gearbox together with CVT does show a significantly increased capability to reduce the NOx emissions by 12.53%. The remaining analysis is focused on the CVT with the optimised 5-speed gearbox.

Table 10: CVT with Optimised Transmissions Results

Transmission	Shifting Strategy	Fuel Consumption	Fuel Reduction	NOx Emission	NOx Reduction
		g	%	g	%
CVT + Optimised 5 Speed	Min Fuel	584.55	-8.83	26.75	-8.79
	Min NOx	587.62	-8.35	26.00	-11.34
CVT + Optimised 6 Speed	Min Fuel	584.53	-8.84	26.24	-10.53
	Min NOx	594.08	-7.35	25.66	-12.53

5.3 5-Speed: Minimum BSFC Strategy

In Figure 6 and 7, the main advantage of using a CVT can be seen by shifting the engine operating region towards more fuel-efficient areas of the BSFC map. The CVT not only aids in allowing for a continuous selection of speed ratios, but also helps to boost the top speed ratios as shown at ~3000rpm, 100Nm. The operation of the CVT becomes clearer further in Figure 7 as it shows a 10 second time frame in which the CVT enables the engine speed to continually increase without having to shift up a gear, whilst moving into a more efficient area of the BSFC map.

*Figure 6: Minimum Fuel Strategy - BSFC map - optimised 5-speed CVT configuration comparison*

Figure 7: Minimum Fuel Strategy - BSFC map close up - optimised 5-speed CVT configuration comparison

The shifting point for the fifth gear using the minimum fuel strategy is shown to be delayed by using the CVT (Figure 8a). Furthermore, the CVT is shown to be used transiently at the lower vehicle speeds; however, when the top speeds of the NEDC are approached at a time > 800s, the CVT is only used at certain constant ratios. Figure 9 shows how the reduced and increased fuel consumption and NOx emission due to CVT is calculated. It is shown that at a certain point the amount of increased fuel consumption and NOx due to the spin is higher than the gained value, hence the CVT can be bypassed. This will also increase the lifespan of the CVT by being able to avoid standing start situations. These instances are shown as broken regions in the Figure 8b. Figure 10 displays a comparison of where the standalone 5-speed gearbox differs from the operation of the CVT with respect to overall fuel consumption and NOx emissions. The fuel consumption is shown to be reduced at urban, rural and motorway speeds whilst the CVT is in use. However, the fuel consumption reduction is most noticeable at time > 800s. This is again the advantage of using a higher top gear ratio at less transient motorway cruising sections of the NEDC.
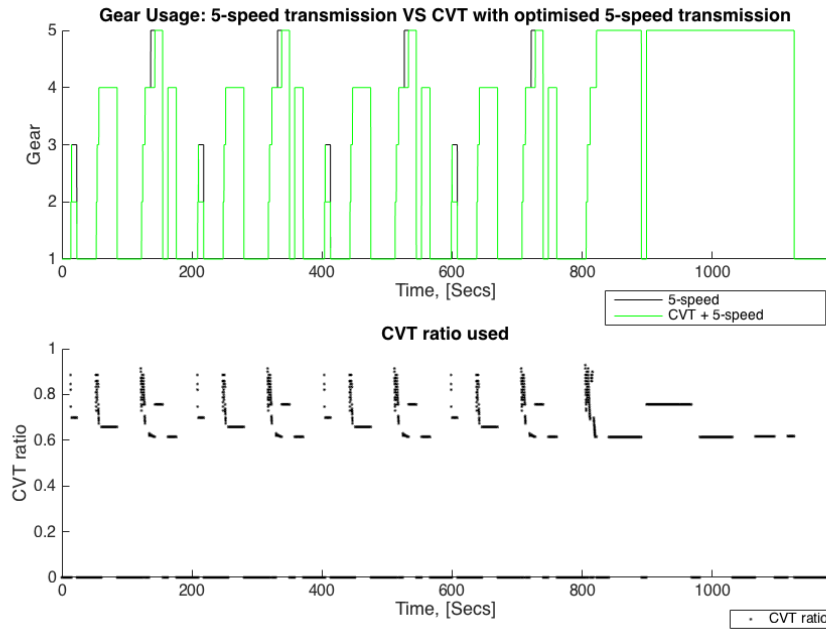

*Figure 8: Minimum Fuel Strategy – (a) Gear and (b) CVT Usage optimised 5-speed configuration comparison*

Figure 9: Minimum Fuel Strategy – (a) Fuel and (b) NOx increase and reductions - CVT usage
Figure 10: Minimum Fuel Strategy - Overall (a) fuel consumption and (b) NOx emissions - optimised 5-speed CVT configuration comparison

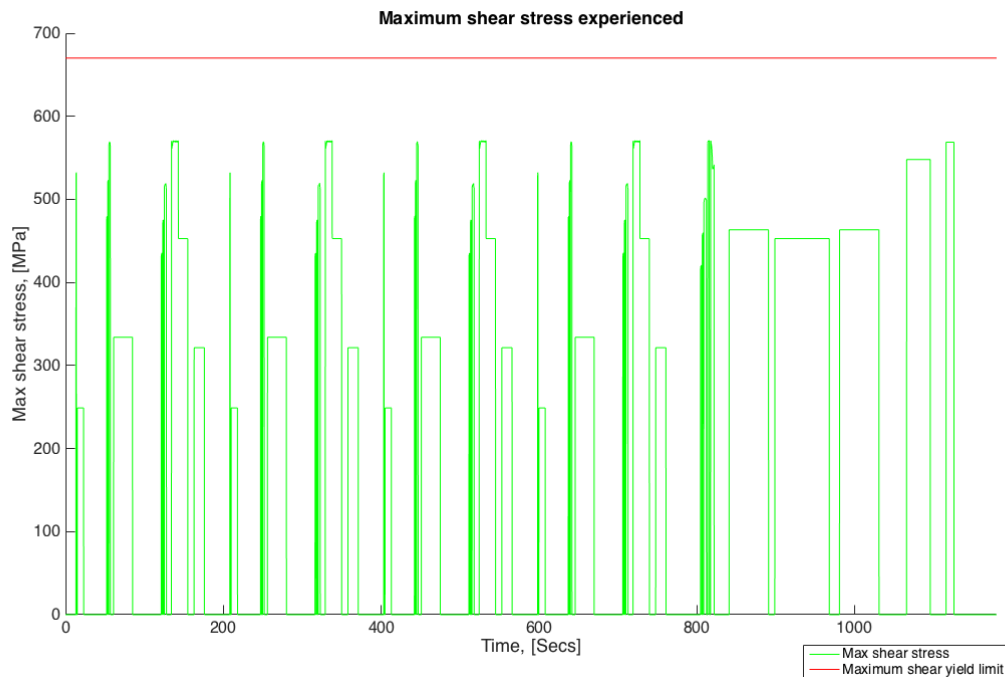

Figure 11: Minimum Fuel Strategy - Maximum shear stress - optimised 5-speed CVT configuration comparison

It is shown, in Figure 11, that the shear maximum stress is not exceeded due to the safety factor of 1.2 employed. Although there does appear to be a significant amount of cyclic loading on the CVTs surfaces. This cyclic loading may become problematic in terms of the life span of the CVT.

5.4 5-Speed: Minimum NOx Strategy

Figure 12 shows that the CVT configured transmission is more able to achieve lower NOx emissions through the increased flexibility of transmission ratios. The CVT allows for a faster increase of engine speed in order to target the reduced NOx emissions as shown in Figure 13. Figure 13 shows the time period of 968.1 to 980.9 seconds of the NEDC cycle. The 5-speed transmission shows a linear increase of engine speed; however, the CVT transmission can continually reduce the speed ratio to its minimum of 0.63. The CVT gives an advantage of reducing the NOx emissions over the 5-speed transmission by 1.3g. Despite the gear shifting strategy targeted towards minimum NOx emissions, the fuel consumption was 11.63g fewer than that of the 5-speed transmissions with a minimum fuel BSFC shifting strategy.

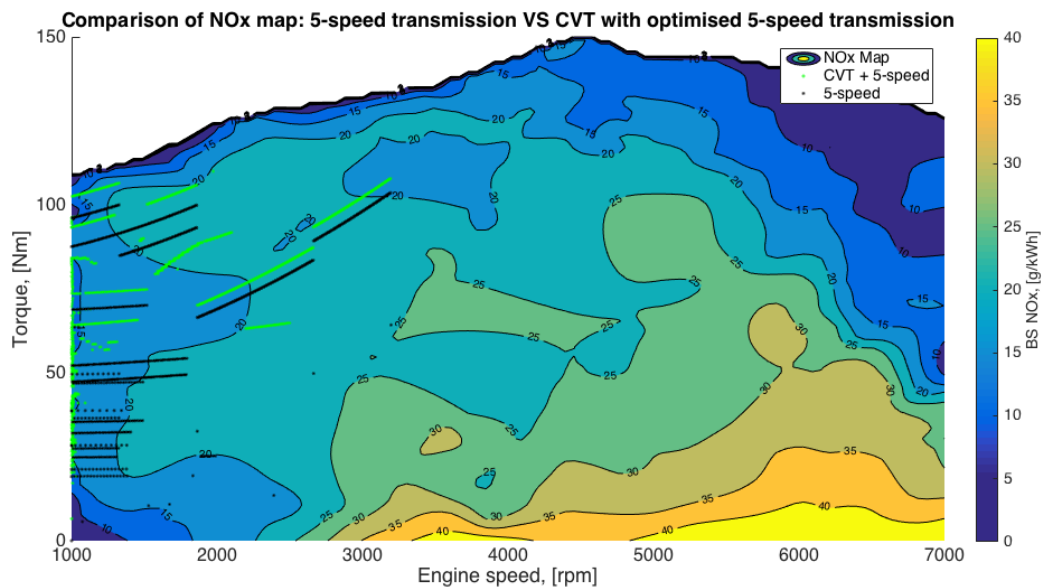

Figure 12: Minimum BSNOx strategy map - 5-speed transmissions VS CVT with optimised 5-speed transmission
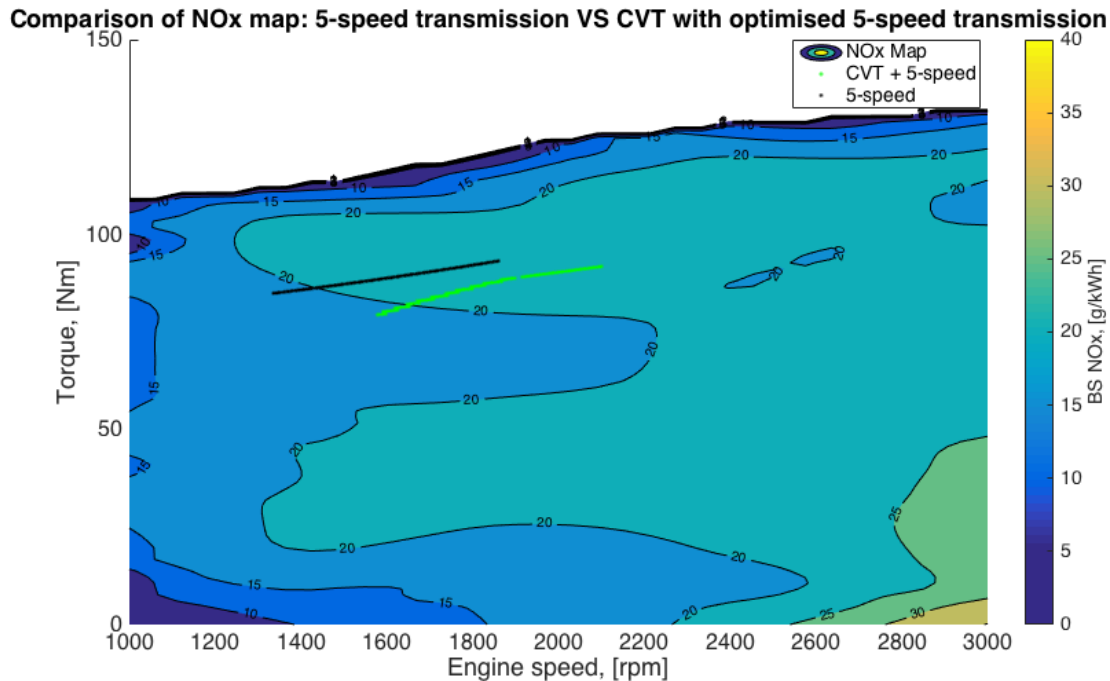

Figure 13: Minimum BSNOx strategy map close up - 5-speed transmissions VS CVT with optimised 5-speed transmission

5.5 6-Speed transmission comparison

The 6-speed transmission reduces the original shifting strategy of the 5-speed fuel and NOx emission values by 7.65% and 7.75% when using the different new gear shifting strategies. Despite this increase in performance from the 6-speed gearbox, due to an increase in discrete gear ratios, it still does not possess the flexibility of the CVT with a 5-speed transmission.

6. Conclusion

The paper details a novel approach in using a CVT mild hybrid transmission with two gear shifting strategies to optimise fuel consumption and NOx emissions and implement the use of a power loss model of a half toroidal CVT. The performance of a vehicle is examined over the NEDC to analyse the use of different shifting strategies and transmission types. The simulation makes use of a power loss model to demonstrate that a half toroidal CVT, in spite of issues regarding their internal inefficiency, can improve the fuel economy and NOx emissions of a vehicle.

The 5 and 6-speed transmissions were optimised to achieve the objective of best fuel economy and reduced NOx emissions. The optimised configurations were then adopted into the series CVT arrangement. This produced an 8.83% improvement in fuel economy and an 11.34% reduction in NOx emissions. Furthermore, the CVT

24

configuration reduced the fuel consumption and NOx emissions in comparison to a conventional 6-speed gearbox by 1.18% and 3.59% respectively. With increasingly more stringent emission regulations for internal combustion engines, the CVT should be considered for its capabilities of increasing the range of operating region at any given instance on the BSFC and BSNOx map over a standard 6-speed transmission.

7. Nomenclature

Symbol	Unit	Description	Symbol	Unit	Description
a	m	Longitudinal acceleration of vehicle	H^*_{cen}		Dimensionless central film thickness
a_e	m	Ellipse main axis	H^*_{min}		Dimensionless minimum film thickness
A_a	m^2	Asperity contact area	h_0	m	Central film thickness
A_f	m^2	Vehicle frontal area	h_{min}	m	Minimum film thickness
b	m	Ellipse minor axis	i		CVT Speed Ratio
c'	J/kgK	Specific heat of solid surfaces	I_D	kgm^2	Inertia of differential unit
dv	m/s	Vector of speed	I_E	kgm^2	Engine inertia
d_x	m	Distance between 2 midpoint x-direction	I_{Eff}	kgm^2	Effective inertia of powertrain
d_y	m	Distance between 2 midpoint y-direction	$I_{F,C}$	kgm^2	Flywheel and clutch inertia
e	m	Minimum Radius of the half toroid	I_P	kgm^2	Propshaft inertia
E'	Pa $^{-1}$	Reduced elastic modulus	I_s	kgm^2	Driveshaft inertia
E_1	GPa	Young's modulus of material 1	I_T	kgm^2	Transmission inertia in the selected gear
E_2	GPa	Young's modulus of material 2	I_w	kgm^2	Combined inertia of the wheels and brake discs
f	Rad	Angle of contact from normal	k		Ellipticity parameter
f_1	Nm	Friction required by system	k'	W/mK	Surface material thermal conductivity
F_2		Asperities Gaussian distribution	M_{eng}	kg	Maximum engine speed
$F_{5/2}$		Gaussian Distribution - statistical function	M_{NOx}	kg	Mass of generated NOx
F_b	Nm	Boundary friction	M_v	kg	Vehicle mass
F_G	Nm	Gradient force	$n_{contactpoints}$		Number of contact points
F_R	Nm	Rolling resistance	N_{Eng}	Rpm	Engine idling speed
F_s	Nm	Static friction	NOx	g/kWh	Rate of production of NOx
F_v	Nm	Viscous friction	$n_{rollers}$		Number of rollers
F_x	Nm	Traction	P	kW	Total spin power loss
g	m/s^2	Gravitational constant			
G_e		Dimensionless material			

Symbol	Unit	Description	Symbol	Unit	Description
P_{Eng}	kW	Engine power	U_e		Dimensionless speed
P_m	Pa	Pressure in the contact	$\mathbf{V}$		Entrainment vector
P_{max}	Pa	Maximum pressure	v	m/s	Vehicle velocity
q	Rad	Power roller angle	v_1		Poisson's ratio of material 1
R'	m	Reduced Radius	v_2		Poisson's ratio of material 2
r(i,j)	m	Radius from polar centre	W	N	Load
R_1	m	Effective radius of input disk	W_a	N	Asperity load
R_{12}	m	Radius of cavity	W_e		Dimensionless load
R_{21}	m	Roller curvature	W_h		Hydrodynamic load
R_{22}	m	Radius of the roller	c_D	N	Aerodynamic drag
R_3	m	Effective radius of output disk	$\tilde{p}$	Pa	Average pressure
R_e	m	Auxiliary orthogonal radii normal to V	Δt	s	Time step of simulation
R_s	m	Auxiliary orthogonal radii normal to V	ω_{disk}	Rad/s	Input disk angular velocity
r_w	m	Laden tyre radius	$\bar{k}$	Ns^{-1}°C^{-1}	Lubricant thermal conductivity
R_x	m	Principal relative radii of curvature	m_{fuel}	g	Mass of fuel burnt
R_y	m	Principal relative radii of curvature	$\emptyset$	Rad	Possible CVT angles
S_{disk}	m/s	Speed of disk	ω_{roller}	Rad	Roller angular velocity
S_{roller}	m/s	Speed of roller	ω_{spin}	Rad/s	Spin angular velocity
T_{Eng}	Nm	Engine torque			
U	m/s	Rolling speed of disk in the x direction			

Greek Symbols

Symbol	Unit	Description
η		Overall Powertrain Efficiency
θ_{road}	°C	Slope of hill
μ		Rolling resistance coefficient
ρ	kg/m^3	Air density
α	Pa^{-1}	Pressure-viscosity coefficient
$\bar{\alpha}$	Pa^{-1}	Average pressure coefficient
β	m	Average asperity tip radius
ε	(-)	Slope of the lubricant limiting shear stress–pressure dependence
$\bar{\varepsilon}$	(-)	Simplified elliptical integral
$\bar{\eta}$	Pa.s	Average viscosity
η_0	Pa.s	Entry viscosity of the lubricant
λ	(-)	Stribeck's oil film parameter
λ_{cr}	(-)	Critical Stribeck's parameter
μ_m	(-)	Maximum coefficient of friction
σ	m	Composite RMS surface roughness
ρ'	kg/m^3	Surface material density
τ	N/m^2	Shear stress
τ (i,j)	N/m^2	Shear stress at a grid point
τ_L	N/m^2	Limiting shear stress
τ_0	N/m^2	Eyring shear stress
$\overline{\tau_0}$	N/m^2	Average Eyring stress
θ_v	degrees	Angle of entrainment vector
ξ	(-)	Parameter xi
ξ_1	(-)	Asperity density per unit area
φ_{Input}	(-)	Input Ratio
φ_{CVT}	(-)	CVT Speed Ratio
φ_{Gear}	(-)	Gear Ratio
